# Atlantic States Marine Fisheries Commission <br> Atlantic Menhaden TC and SAS Meeting Draft Agenda 

June 26-27, 2013
1:00 p.m. - 6:00 p.m. (6/26) 8:00 a.m. - 5:00 p.m. (6/27)

The times listed are approximate; the order in which these items will be taken is subject to change; other items may be added as necessary.

## WEDNESDAY (1-6pm)

1) Welcome/Review Agenda (Micah/Amy)
2) Regional surveys:
a) NEAMAP, ChesMMAP (Rob)
b) SEAMAP (Joey)
c) NEFSC trawl surveys (Matt)
d) Others?
3) State and federal surveys that catch adult menhaden. Every TC rep should prepare a short document containing at least the following info on all agency surveys that collect menhaden (more frequently than rare events).
a) General description (gear, design, temporal \& spatial coverage, targeted species, etc.).
b) Description of menhaden catch rates (e.g., total numbers caught annually, average CPUE, consistently caught vs. one large tow, etc.)
c) Metadata description of each data element available (by time period if changed)
d) Calculate and plot over entire time series the arithmetic and geometric mean catch/effort or other menhaden index appropriate to your study design
e) If available, plot length and age distributions

## THURSDAY (8am-5pm)

4) Continue discussion of state surveys as needed.
5) Icthyoplankton surveys - MARMAP and ECOMON (Hongsheng Bi/Amy/Genny)
6) Power plant impingement/entrainment data (Micah)
7) Review of past and future/planned treatment of JAI seine surveys (note: will include MA and potentially a few other datasets this time) (Rob \& Micah)
8) Tagging data discussion - if time allows, continue planning for short-term analysis of tagging data once digitized. Discuss first steps of database development and query building. Everyone read Dryfoos et al. 1973 and Nicholson 1978 in preparation.

## Massachusetts YOY Winter Flounder Beach Seine Survey

Micah Dean - June 12, 2013

## Description

The Massachusetts Division of Marine Fisheries (MDMF) has completed a seine survey annually since 1976 to provide an age-0 winter flounder recruitment index. The survey takes place each year between June $15^{\text {th }}$ and July $4^{\text {th }}$ and covers six Nantucket Sound estuaries on the south side of Cape Cod - Great Pond, Waquoit Bay, Cotuit Bay, Lewis Bay, Bass River, and Stage Harbor (Figure 1). Seining of intertidal and shallow subtidal zones is conducted from two hours before to two hours after high tide. Forty-nine fixed stations, originally chosen for efficient seining (i.e., smooth sediment generally devoid of attached vegetation) and historic availability of age-0 winter flounder, are proportionately allocated by each estuary's littoral perimeter. A 6.4 meter straight beach seine of 4.8 mm nylon mesh equipped with a weighted lead line footrope to minimize escapement is set and hauled perpendicular to shore from an average depth of 0.9 to 1.2 meters. Abundance data is collected by combining three replicate hauls for each station where area swept is meausred using a standardized spreader line while measuring distance from shore. Abundance data provided for individual stations are converted to a standardized catch rate to account for varied haul length. Catch rates are reported as number per square meter.

Figure 1. Study area for MDMF seine survey showing individual station locations.

## Occurrence of Menhaden

Considering the narrow time frame ( $\sim 10$ days) over which this survey occurs in early summer, it is not ideally suited to provide a meaningful measure of juvenile menhaden abundance. As such, menhaden are infrequently caught, only encountered on 29 ( $2 \%$ ) out of the 1521 completed tows. Menhaden were caught in 13 (42\%) of the 31 years. Although size data are not collected from this survey, only age-0 menhaden have been caught, with most less than 5 cm .

Figure 2. Stratified mean number of menhaden caught per $100 \mathrm{~m}^{2}$ sampled (stratum = estuary).

Table 1. Total number of survey hauls, number of hauls containing menhaden, and the total number of menhaden caught per year, 1982-2012.

# Massachusetts Bottom Trawl Surveys 

Micah Dean - June 12, 2013

## Survey Description

Massachusetts has been conducting annual bottom trawl surveys in the spring and fall since 1978. The survey allocates its sampling effort according to a series of 23 strata in Massachusetts state waters, based on five bio-geographic regions and six depth zones. Trawl sites are allocated in proportion to stratum area and randomly chosen in advance within each sampling stratum. However, the survey gear cannot be deployed over very shallow or very rough bottom types and therefore those areas are not sampled. Tows of standard speed and duration are made with a bottom trawl that has had the same design specifications since the survey began. Total weight and length-frequency are collected for all finfish and a subset of invertebrates. Additional information such as age, sex and maturity are collected from a list of priority species.

## Occurrence of Menhaden

Since this is a bottom trawl survey at the northern end of the range of menhaden, it is not surprising that very few are encountered. In the spring survey, a total of 19 menhaden have been caught on 15 ( $0.4 \%$ ) out of 3,382 tows (Table 1). The fall survey catches somewhat more menhaden, with a total of 2,550 caught on 54 ( $1.7 \%$ ) of 3,158 tows. However, almost $90 \%$ of these fish were caught on two individual tows in a single year (2007). Furthermore, the majority of menhaden caught by the fall survey are not adults (Figure 1). Considering the rarity of menhaden caught by these surveys, it is unlikely that these data will prove useful in the development of an index of menhaden abundance (Figure 2).

Table 1. Annual number of tows and occurrence of menhaden in the spring and fall Massachusetts bottom trawl surveys.

CT, fishery-independent adult menhaden - LIS - 6/10/2013

## CONNECTICUT LONG ISLAND SOUND TRAWL SURVEY (LISTS)

The Connecticut DEEP Marine Fisheries Division has conducted a fisheries-independent Trawl Survey in Long Island Sound since 1984. The Long Island Sound Trawl Survey (LISTS) provides fishery independent monitoring of important recreational species, as well as annual total counts and biomass for all finfish taken in the Survey. LISTS also collects data on all living resources seen during the Survey, including total biomass for invertebrates. The Long Island Sound Trawl Survey encompasses an area from New London, Connecticut (longitude $72^{\circ} 03^{\prime}$ ) to Greenwich, Connecticut (longitude $73^{\circ} 39^{\prime}$ ). The sampling area includes Connecticut and New York state waters from 5 to 46 meters in depth and is conducted over mud, sand and transitional (mud/sand) sediment types (see example, Figure 1). Currently, Long Island Sound is surveyed in the spring (April-June) and fall (September-October) periods with 40 sites sampled monthly for a total of 200 sites annually.

The sampling gear employed is a 14 m otter trawl with a 51 mm codend (Table 1). To reduce the bias associated with day-night changes in catchability of some species, sampling is conducted during daylight hours only (Sissenwine and Bowman 1978). LISTS employs a stratified-random sampling design. The sampling area is divided into $1.85 \times 3.7 \mathrm{~km}$ ( $1 \times 2$ nautical miles) sites, with each site assigned to one of 12 strata defined by depth interval ( $0-9.0 \mathrm{~m}, ~ 9.1-18.2 \mathrm{~m}, 18.3-27.3 \mathrm{~m}$ or, $27.4+\mathrm{m}$ ) and bottom type (mud, sand, or transitional as defined by Reid et al. 1979). For each monthly sampling cruise, sites are selected randomly from within each stratum. The number of sites sampled in each stratum was determined by dividing the total stratum area by 68 $\mathrm{km}^{2}$ (20 square nautical miles), with a minimum of two sites sampled per stratum (Table 2). Discrete stratum areas smaller than a sample site are not sampled.

Figure 1. Example of LISTS site map and sites selected and completed for one month, June 2011

Table 1. LISTS specifications for Wilcox 14 m high-rise trawl net and associated gear

| Component | Description |
| :--- | :--- |
| Headrope | 9.1 m long, 13 mm combination wire rope |
| Footrope | 14.0 m long, 13 mm combination wire rope |
| Sweep | Combination type, 9.5 mm chain in belly, 7.9 mm chain in wing |
| Floats | 7 floats, plastic, 203 mm diameter |
| Wings | 102 mm mesh, \#21 twisted nylon |
| Belly | 102 mm mesh, \#21 twisted nylon |
| Tail Piece | 76 mm mesh, \#21 twisted nylon |
| Codend | 51 mm mesh, \#54 braided nylon |
| Ground Wires | 18.2 m long, $6 \times 7$ wire, 9.5 mm diameter |
| Bridle Wires: | top legs 27.4 m long, $6 \times 7$ wire, 6.4 mm diameter |
| Bottom Legs | 27.4 m long, $6 \times 7$ wire, 11.1 mm, rubber disc type, 40 mm diameter |
| Doors | Steel "V" type, 1.2 m long x 0.8 m high, 91 kg |
| Tow Warp | $6 \times 7$ wire, 9.5 mm diameter |

Table 2. The number of sites scheduled for sampling each month within the 12 depth-bottom type strata.

|  | Depth Interval (m) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Bottom type | $\mathbf{0 - 9 . 0}$ | $\mathbf{9 . 1} \mathbf{- 1 8 . 2}$ | $\mathbf{1 8 . 3 - 2 7 . 3}$ | $\mathbf{2 7 . 4 +}$ | Totals |
| Mud | 2 | 3 | 5 | 5 | 15 |
| Sand | 2 | 2 | 2 | 2 | 8 |
| Transitional | 3 | 5 | 5 | 4 | 17 |
| Totals | $\mathbf{7}$ | $\mathbf{1 0}$ | $\mathbf{1 2}$ | $\mathbf{1 1}$ | $\mathbf{4 0}$ |

Menhaden catch during the Long Island Sound Trawl Survey average about 400 fish annually, however, two years of higher catches were observed; 1992 (1,115 fish) and 1999 ( 1,187 fish). LISTS has recorded a catch of 11,242 menhaden from all tows since 1984. Typically the fall survey records higher abundance ( $28.5 \%$ positive tows) with the majority ( $71 \%$ ) of the catch being fish less than 20 centimeters long. Only a few menhaden are recorded during spring cruises ( $7.3 \%$ positive tows), however, seventy-five percent of the springtime catch are adults. Menhaden length measurements have been recorded on every tow since 1996 (Figure 2). The average fall geometric mean catch since 1984 has been 0.68 menhaden/tow and the average biomass since 1992 (biomass was first recorded in 1992) has been $0.27 \mathrm{~kg} /$ tow (Figure 3). Arithmetic mean catch per tow since 1984 is 3.43 menhaden during the fall and 0.29 menhaden per tow during the spring.

Tables, including raw catch data (zero-filled) and length data, are provided along with total catch, numbers of tows, and indices of abundance in attached file (see: CT_LISTS_MEN.xlsx).
For specific details on methods see:

# Survey Descriptions for NYSDEC Fishery Independent Surveys <br> That capture Menhaden Data 

## NYSDEC Peconic Bay Small Mesh Trawl Survey

Years Sampled: 1987 - 2012
Gear Type: 4.8 m semi-balloon shrimp trawl, the body has 3.8 cm mesh, the codend has 3.2 cm mesh, and the codend liner has 1.3 cm mesh. The footrope is 0.95 cm rope that is 6.4 m long, with legs extended 0.9 m and wire rope thimbles spliced at each end, 0.6 cm chain hung in loop style on the footrope. The net was towed for 10 minutes at approximately 2.5 knots. The vessel used was a 10.7 m lobster style workboat.

## Spatial Coverage: Peconic Bay

Temporal coverage: May through October
Sample Design: Random survey based on a block grid design. The survey area was divided into 77 sampling blocks with each block measuring 1 ' latitude and 1 ' longitude.

Sample frequency and number: 16 stations were randomly chosen each week to sample
Information Collected: All finfish species are identified and counted. Environmental information (surface and bottom temperature, salinity, dissolved oxygen, and secchi disc readings) were recorded at each station.

Changes in Sample Design: From 1987 - 1990 the net was set by hand and retrieved using a hydraulic lobster pot hauler. From 1991 to the present the net was set and retrieved using hydraulic trawl winches and an A-frame. Due to vessel problems, the survey was not conducted during the following time periods: 2005 from mid-July through October, 2006 from May through mid-July, 2008 from May through mid-August, and 2010 during May.

## NYSDEC Western Long Island Beach Seine Survey

Years Sampled: 1984-2012
Gear Type: 200ft x 10 ft beach seine with $1 / 4$ inch square mesh in the wings, and $3 / 16$ inch square mesh in the bunt. The seine is set by boat in a " $U$ " shape along the beach and pulled in by hand.

Spatial Coverage: Little Neck (LNB) and Manhasset Bay (MAN) on the north shore of Long Island (WLIS), and Jamaica Bay (JAM) on the south shore. Other bays have been sampled on a shorter time frame.

Temporal Coverage: May through October. Pre 2000 sampling was conducted 2 times per month during May - June and once a month July - October. Sampling from 2000 - 2012 was conducted 2 times per month from May - October.

Sample Design: Fixed site survey. Generally 5 - 10 seine sites are sampled in each bay on each sampling trip.

Information Collected: All finfish species are identified and counted. Environmental information (air and water temperature, salinity, dissolved oxygen, tide stage, wind speed and direction, and wave height) has been recorded at each station. Bottom type, vegetation type, and percent cover have been recorded qualitatively since 1988.

## NYSDEC Lower Hudson River Beach Seine Survey

Years sampled: 1979 to the present, consistent methodology starting in 1985
Gear type: $200 \mathrm{ft} x 10 \mathrm{ft}$ beach seine with $1 / 4$ inch square mesh in the wings, and $3 / 16$-inch square mesh in the bunt. Bunt is offset. The seine is set by boat in a "U" shape along the beach and pulled in by hand.

Spatial coverage: The lower Hudson River from Dobbs Ferry (River Mile (RM) 18) to Haverstraw (RM 40)

Temporal coverage: Nine bi-weekly trips from Mid-July through early November. Pre-1985 sampling was conducted during six bi-weekly trips from August through early November

Sample design: Fixed site survey.
Sample frequency and number: 25 seine sites were planned to be sampled during each bi-weekly sampling trip. Twenty-five stations were not sampled each bi-weekly trip due to weather or equipment problems.

Information collected: All finfish species identified and counted, Environmental information (air and water temperature, tide stage, wind speed and direction, and wave height) has been recorded at each station. Salinity has been recorded consistently since 1985, and dissolved oxygen has generally been recorded since 1987, except during 1996, 1997 and the end of 1998 due to equipment problems. Bottom type, vegetation type, and percent cover has been recorded qualitatively since 1988

## Measure of central tendency and CI: Arithmetic and geometric mean

Changes in sample design: Twenty-five stations were not sampled each bi-weekly trip due to weather or equipment problems, temporal coverage increased from six bi-weekly trips starting in August to nine bi-weekly trips starting in mid-July from 1985 to the present. Starting consistently in 2000 Menhaden age groups were broken out as 0 -YOY or 1-OLDER.

Survey: New Jersey Delaware Bay Trawl
Gear: 16’ otter trawl
Time series: 1991 - present
Frequency: Monthly, April through October
Design: 11 fixed stations
Location: Shoal areas in NJ portion of DE Bay
Variables: Date, station, depth, salinity, temperature, DO, number, lengths
Metadata: To my knowledge, everything has been consistent throughout survey. Sampling was a bit erratic in early years, but May and June seemed stable based on N tows by station.
Synopsis: High frequency of negative tows ( $\sim 75 \%$ overall); few fish over 60 mm ( $\sim 3 \%$ of all fish); Doesn’t appear useful as adult index; never been used as juvenile index but perhaps worth investigating

Survey: New Jersey Ocean Trawl
Gear: "three in one" trawl, 30.5m foot rope
Time series: August 1988 - present
Frequency: 5 cruises per year (Jan, Apr, Jun, Aug, Oct)
Design: $\quad$ Stratified random by depth; utilizes NEFSC inshore trawl strata
Location: Cape May to Sandy Hook, shore to 90’ isobath
Variables: Date, stratum, station, vessel, tow time, depth, lat/long, temperature, salinity, DO, number, total weight, lengths
Metadata: Changes to survey timing in first few years (consistent since 1991); 5 different vessels over survey history (same vessel since 2002); survey dates shift due to vessel availability and weather Synopsis: Low percentage of positive tows (<20\% overall); few fish $>150 \mathrm{~mm}$ YOY cut off in fall ( $<15 \%$ ); Bottom trawl in "deep" water not effective at catching pelagics; however, there is some evidence that $160+$ CPUE lags NJ YOY index by 1 year. Also, Jan fish index appears to lag Oct index, but not convinced they are same fish since LFs (all years combined) don't line up.

Seine YOY vs October Trawl 150+

Survey: New Jersey Juvenile Striped Bass Seine Survey
Gear: $\quad 100$ ' bagged seine, $1 / 4$ inch mesh
Time series: 1980-present
Frequency: Twice per month, June to November
Design: Different throughout history, currently 32 fixed stations; three regions based on salinity Location: Delaware River, RM 53.5 (Salem Nuclear) to 126 (Trenton)
Variables: Year, region, sample round, fixed/random, water temp, salinity, DO, number, lengths Metadata: Several changes to survey design, including:

- 1980-1986, "haphazard" sampling
- 1987-1990, replicate tows at 16 fixed stations $2 x$ per month, mid July to mid Nov
- 1991-1997, fixed and random design, single tows, $2 x$ per month, Aug - Oct; $50 \%$ of effort in region 2
- 1998 - present, single tows at 32 fixed stations, 2x per month, June to November Current sites have been relatively consistent since 1998, and many of those have sampling histories back to the 1980s (but not always continuous). Occasionally we "lose" a beach and have to find alternate site. Generally, menhaden catches in upper (fresh water) region are low and drop that region for YOY index. Generally use only first tow at a site during period replicates were performed. Have looked at using all sites vs only "consistent" sites for YOY calculation. Use TC approved YOY length cut-offs to weed out adults. Prior to 2001, only min and max lengths were recorded.

DELAWARE RIVER RECRUITMENT SURVEY SAMPLING AREA

| novembel | 102 | 118 |  | 220 |
| novembel | 1 | 1 |  | 2 |

Did not calculate indices since it is almost entirely YOY.

Survey: Rutgers Trawl Survey
Gear: $\quad 16$ foot trawl, 6 mm codend mesh
Time series: 1988-1990, 1996-present
Frequency: Annually, July and September
Design: $\quad 30+$ fixed station, 4 replicate 2-minute tows per site per month
Location: primarily Great Bay estuary
Variables: Date, time, number, salinity, temperature, DO
Metadata: New stations added when restarted in 1996

Have not calculated indices yet. Waiting for data request to be fulfilled. Don't expect there to be too many adults.

Survey: Rutgers Ichthyoplankton Survey
Gear: $\quad 1$-m diameter plankton net, 1 mm mesh
Time series: 1989-present
Frequency: Weekly, year round on night time flood tide
Design: 1 fixed station, 3 replicates per night at mid water beginning 1 hour after predicted low
tide
Location: Little Sheepshead Creek (Great Bay / Little Egg Harbor, NJ)
Variables: Date, time, flow meter count, number, salinity, temperature, DO
Metadata: A few modifications to survey design in early years, but consistent since 4/2002.
Originally, surface and bottom nets deployed simultaneously for 5 replicates per night, and net right as tide turned. Processing of samples is backlogged a few years, so don't have most recent years of data.

No indices calculated yet. Definitely not an adult index, so didn't need it for this meeting. Still waiting for data request to be fulfilled, and will develop YOY index.

# MARYLAND JUVENILE STRIPED BASS SURVEY 

prepared by Eric Q. Durell

## INTRODUCTION

The primary objective of this survey is to document annual year-class success for young-of-the-year (YOY) striped bass (Morone saxatilis) in Chesapeake Bay. Annual indices of relative abundance provide an early indicator of future adult stock recruitment (Schaefer 1972; Goodyear 1985) and document annual variation and long-term trends in abundance and distribution. The juvenile striped bass survey also documents relative abundance of many other fish species in Chesapeake Bay. Over 100 fish species have been collected since 1954.

## METHODS

## Sample Area and Intensity

Juvenile indices are derived annually from sampling at 22 fixed stations within Maryland's portion of the Chesapeake Bay (Figure 1). They are divided among four of the major spawning and nursery areas: seven each in the Potomac River and Head of Bay areas and four each in the Nanticoke and Choptank rivers. Stations have been sampled continuously since 1954, with changes in some station locations.
Sampling is monthly, with rounds (sampling excursions) occurring during July (Round I), August (Round II), and September (Round III). Replicate seine hauls, a minimum of thirty minutes apart, are taken at each site on each sample round. This produces a total of 132 samples from which Bay-wide means are calculated.

From 1954 to 1961, juvenile surveys included various stations and rounds. Sample sizes ranged from 34 to 46 . Indices derived for this period include only stations which are consistent with subsequent years. In 1962, stations were standardized and a second sample round was added for a total of 88 samples. A third sample round, added in 1966, increased sample size to 132.

Auxiliary stations have been sampled on an inconsistent basis and are not included in survey indices. These data enhance geographical coverage in rivers with permanent stations or provide information from other river systems. They are also useful for replacement of permanent stations when necessary. Replicate hauls at auxiliary stations were discontinued in 1992 to conserve time and allow increased geographical coverage of spawning areas. Auxiliary stations were sampled at the Head of Bay (Susquehanna Flats and one downstream station) and the Patuxent River (Table 1, Figure 1).

## Sample Protocol

A $30.5-\mathrm{m}$ x $1.24-\mathrm{m}$ bagless beach seine of untreated $6.4-\mathrm{mm}$ bar mesh was set by hand. One end was held on shore while the other was fully stretched perpendicular from the beach and swept with the current. Ideally, the area swept was equivalent to a 729 m quadrant. When depths of $1.6-\mathrm{m}$ or greater were encountered, the offshore end was deployed along this depth contour. An estimate of distance from the beach to this depth was recorded.

Striped bass and selected other species were separated into 0 and 1+ age groupings. Ages were assigned from length-frequencies and verified through scale examination. Age 0 fish were measured from a random sample of up to 30 individuals per site and round. All other finfish were identified to species and counted.

Additional data were collected at each site and sample round. These included: time of first haul, maximum distance from shore, weather, maximum depth, surface water temperature ( ${ }^{\circ} \mathrm{C}$ ), tide stage, surface salinity (ppt), primary and secondary bottom substrates, and submerged aquatic vegetation within the sample area (ranked by quartiles). Dissolved oxygen (DO), pH, and turbidity (secchi disk) were added in 1997. All data were entered and archived in Statistical Analysis System (SAS) databases (SAS 1990).

## Estimators

The most widely used striped bass 'juvenile index' is the arithmetic mean (AM). The AM has been used to predict harvest in New York waters (Schaefer 1972). Goodyear (1985) validated this index as a predictor of harvest in the Chesapeake Bay. The AM is an unbiased estimator of the mean regardless of the underlying frequency distribution (McConnaughey and Conquest 1992). The AM, however, is sensitive to high sample values (Sokol and Rolhf 1981). Additionally, detection of significant differences between annual arithmetic means is often not possible due to high variances (Heimbuch et al. 1983; Wilson and Wiesburg 1991). The geometric mean (GM) has been adopted by the Atlantic States Marine Fisheries Commission (ASMFC) Striped Bass Technical Committee as the preferred index of relative abundance to model stock status. The GM is calculated from the $\log _{e}(x+1)$ transformation, where x is an individual seine haul catch. One is added to all catches in order to transform zero catches, because the log of 0 does not exist (Ricker 1975). Since the $\log _{\mathrm{e}}$-transformation stabilizes the variance of catches (Richards 1992) the GM estimate is more precise than the AM and is not as sensitive to a single large sample value. It is almost always lower than the AM (Ricker 1975). The GM is presented with $95 \%$ confidence intervals (CIs). These are calculated as antilog $\left(\log _{e}(x+1)\right.$ mean $\pm 2$ standard errors), and provide a visual depiction of sample variability.

A third estimator, the proportion of positive hauls (PPHL), is the ratio of hauls containing juvenile striped bass to total hauls. Because the PPHL is based on the binomial distribution, it is very robust to bias and sampling error and greatly reduces variances (Green 1979). Its use as supplementary information is appropriate since seine estimates are often neither normally nor log-normally distributed (Richards 1992).

Comparison of these three indices is one method of assessing their accuracy. Similar trends among indices create more certainty that indices reflect actual changes in population abundance. Greatly diverging trends may identify error in one or more of the indices. Differences among annual means were tested with analysis of variance (GLM; SAS 1990) on the $\log _{e}(x+1)$ transformed data. Terms were considered significant at the $p=0.05$ level.
Atlantic menhaden data
Geometric means for the Head of the Bay, Choptank River, Nanticoke River, Potomac River, Patuxent River and Bay-wide are presented on Figures 2-7.

# MARYLAND JUVENILE STRIPED BASS SURVEY DATA DOCUMENTATION 

The Juvenile Striped Bass Survey data set, SEINSTD.SD2, is saved as a SAS data file.

## Sample Protocol

A $30.5-\mathrm{m}$ x $1.24-\mathrm{m}$ bagless beach seine of untreated $6.4-\mathrm{mm}$ bar mesh was set by hand. One end was held on shore. The other was fully stretched perpendicular from the beach and swept with the current. When depths of $1.6-\mathrm{m}$ or greater were encountered, the offshore end was deployed along this depth contour. An estimate of distance from the beach to this depth was recorded. Replicate seine hauls, a minimum of thirty minutes apart, are taken at each site on each sample round. Sampling is monthly, with rounds (sampling excursions) occurring during July (Round I), August (Round II), and September (Round III).

Striped bass and selected other species were separated into 0 and 1+ age groupings. Ages were assigned from length-frequencies and verified through scale examination. Age 0 fish were measured from a random sample of up to 30 individuals per site and round. All other finfish were identified to species and counted.

Additional data were collected at each site and sample round. These included: time of first haul, maximum distance from shore, weather, maximum depth, surface water temperature $\left({ }^{\circ} \mathrm{C}\right)$, tide stage, surface salinity (ppt), primary and secondary bottom substrates, and submerged aquatic vegetation within the sample area (ranked by quartiles). $\mathrm{DO}, \mathrm{pH}$, conductivity, and turbidity (secchi disk) were added in 1997.

The following is a list of variable names and attributes found in the data set:

| VARIABLE \# | VARIABLE | COMMENTS, UNITS |
| :---: | :--- | :--- |
|  |  |  |
| 41 | AGE | Applied to selected species only, years |
| 17 | BOTTYPE1 | Primary bottom type |
| 18 | BOTTYPE2 | Secondary bottom type |
| 34 | CONDUCT | Conductivity, $\mu \mathrm{S} / \mathrm{cm}$ |
| 20 | COUNTY |  |
| 28 | DAY |  |
| 24 | DEPMAX | Maximum depth net was deployed, feet |
| 10 | DISOFFS | Perpendicular distance from shore, meters |
| 37 | DO | Dissolved oxygen, mg/L |
| 39 | GEAR | BCHS=beach seine |
| 31 | GEARLEN | Length of gear, meters |
| 35 | HATCH | designates origin of hatchery raised fish |
| 11 | HAULNO | First or second seine haul at site |

VARIABLE \# VARIABLE

| 38 | JISECCI | secchi disk reading, meters (9.99 when secchi>site) |
| :---: | :--- | :--- |
| 30 | JULDATE | Julian date |
| 32 | LATSTRT | latitude; degrees, minutes, decimal seconds |
| 33 | LONGSTRT | longitude; degrees, minutes, decimal seconds |
| 23 | MESH | stretch mesh size of net, inches |
| 27 | MONTH |  |
| 21 | NOAA | Area code designated by NOAA |
| 36 | PH |  |
| 1 | RIVER |  |
| 22 | RIVMILE | Distance from mouth of river to site, miles |
| 26 | ROUND | Sample round, see protocol |
| 7 | SAL | Salinity, ppt |
| 9 | SAVPCT | Estimated SAV coverage, by quartiles |
| 2 | SITENAME |  |
| 29 | SITENO | Site number |
| 15 | SITETYPE | Indicates permanent or auxiliary site |
| 14 | SIZEMAX | Total length of longest specimen of a species, mm |
| 13 | SIZEMIN | Total length of smallest specimen of a species, mm |
| 12 | SPECCNT | Total number of a species collected |
| 25 | SPECNAME | Species name |
| 19 | STRMCODE | Code for body of water where site is located |
| 16 | SYSTEM | Indicates river or other geographical grouping of sites |
| 40 | TEMPWATR | Subsurface water temperature, degrees C |
| 6 | TIDE | Tide stage |
| 3 | TIMESTRT | Time of first seine haul, military |
| 8 | VISIB | Very old, seldom used variable, units unclear |
| 4 | WEATHER |  |
| 5 | WINDSPD | Wind speed, no longer used |
| 42 | YEAR | Changed to 4-digit in 2000 |

## Maryland Coastal Bays Trawl and Seine Survey Results in application to Atlantic menhaden ${ }^{1}$

This survey was developed to characterize fishes and their abundances in Maryland's Coastal Bays, facilitate management decisions, and protect finfish habitats. The Maryland Department of Natural Resources (MDNR) Fisheries Service has conducted the Coastal Bays Fisheries Investigations (CBFI) Trawl and Beach Seine Survey in Maryland’s Coastal Bays since 1972, sampling with a standardized protocol since 1989. These gears target finfish although bycatch of crustaceans, molluscs, sponges, and macroalgae are common. Over 130 adult and juvenile species of fishes, 26 molluscs, 20 macroalgae species, and 29 species of arthropods have been collected since 1972. This survey was designed to meet the following three objectives:

1. characterize the stocks and estimate relative abundance of juvenile and adult marine and estuarine species in the Coastal Bays and near-shore Atlantic Ocean;
2. develop annual indices of age and length, specific relative abundance and other needed information necessary to assist in the management of regional and coastal fish stocks; and
3. delineate and monitor areas of high value as spawning, nursery and/or forage locations for finfish in order to protect against habitat loss or degradation.

## Study Area

Maryland’s Coastal Bays are comprised of Assawoman Bay, Isle of Wight Bay, Sinepuxent Bay, Newport Bay, and Chincoteague Bay. Also included are several important tidal tributaries: St. Martins River, Turville Creek, Herring Creek, and Trappe Creek. Covering approximately 363 $\mathrm{km}^{2}\left(140 \mathrm{mi}^{2}\right)$, these bays and associated tributaries average only 0.9 m ( 3 feet) in depth and are influenced by a watershed of only $453 \mathrm{~km}^{2}\left(175 \mathrm{mi}^{2}\right.$; MDNR 2005). The bathymetry of the Coastal Bays is characterized by narrow channels, shallow sand bars, and a few deep holes.

Two inlets provide oceanic influences to these bays. Ocean City Inlet is formed at the boundaries of south Fenwick Island and north Assateague Island and is located at the convergence of Isle of Wight Bay and Sinepuxent Bay. Chincoteague Inlet, in Virginia (VA), is approximately $56 \mathrm{~km}(34 \mathrm{mi})$ south of the Ocean City Inlet.

The Coastal Bays are separated from the Atlantic Ocean to the east by Fenwick Island (Ocean City) and Assateague Island. Ocean City, Maryland is a heavily developed commercial area and the center of a $\$ 2$ billion dollar tourism industry catering to approximately 12 million visitors annually (MCBP 2005). Assateague Island is owned by the State of Maryland and the National Park Service (NPS). These entities operate one state (Assateague State Park) and two national parks (Assateague Island National Seashore and Chincoteague National Wildlife Refuge). These properties have campgrounds, small buildings, dunes, beach front with some Off Road Vehicle (ORV) access, and marshes.

The Coastal Bays western shoreline habitat consists of forest, Spartina spp. marshes, small islands, residential development, and marinas. Assawoman Bay is bordered by Maryland and Delaware and is characterized by farmland, Spartina spp. marshes, a few small islands, and commercial/residential development. Isle of Wight Bay south into Sinepuxent Bay is a heavily

[^0]developed commercial/residential area. Two seafood dealers, a public boat launch, and approximately 20 to 50 transient and permanent commercial fishing vessels utilize the commercial harbor located directly west of the Ocean City Inlet. In addition to the commercial harbor, the majority of marinas in Ocean City are located in Isle of Wight Bay. Residential development expansion has begun moving south into Chincoteague Bay. Vast Spartina spp. marshes and numerous small islands characterize Chincoteague Bay.

Submerged Aquatic Vegetation (SAV) and macroalgae (seaweeds) are common plants in these bays that provide habitat and foraging sites for fishes and shellfish (Beck et al. 2003). Two species of SAV are common in Maryland's Coastal Bays: widgeon grass, Ruppia maritima, and eelgrass, Zostera marina (MDNR 2005). Common genera of macroalgae include Chaetomorpha, Agardhiella, Gracilaria, and Ulva.

## Data Collection

A 25 foot C-hawk with a 225 horsepower Evinrude E-tec engine is used for transportation to the sample sites and gear deployment. Latitude and longitude coordinates (waypoints) in decimal degrees, minutes, and fraction of minutes (ddmm.mmm) are used to navigate to sample locations. A GPS is used for navigation, marking sites, and monitoring speed.

## Gears

Trawl
Trawl sampling is conducted at 20 fixed sites throughout Maryland's Coastal Bays on a monthly basis from April through October (Figure 1). Samples are usually taken beginning the third week of the month. The boat operator takes into account wind and tide (speed and direction) when determining trawl direction. A standard $4.9 \mathrm{~m}(16 \mathrm{ft})$ semi-balloon trawl net is used in areas with a depth of greater than $1.1 \mathrm{~m}(3.5 \mathrm{ft})$. Each trawl has a standard 6-minute ( 0.1 hr ) tow at a speed of approximately 2.8 knots. Speed is monitored during tows using the GPS. Waypoints marking the sample start (gear fully deployed) and stop (point of gear retrieval) locations are taken using the GPS to determine the area swept (hectares). Time is tracked using a stopwatch which was started at full gear deployment.

## Seine

Seines are used to sample the shallow regions of the Coastal Bays frequented by juvenile fishes. Shore beach seine sampling is conducted at 19 fixed sites beginning in the second weeks of June and September (Figure 1).

A 30.5 m X 1.8 m X 6.4 mm mesh ( 100 ft X 6 ft X 0.25 in . mesh) bag seine is used at 18 fixed sites in depths less than 1.1 m ( 3.5 ft .) along the shoreline. However, some sites necessitated varying this routine to fit the available area and depth. GPS coordinates are taken at the start and stop points as well as an estimated percent of net open.

## Sample Processing

Fishes and invertebrates are identified, counted, and measured for Total Length (TL) using a wooden millimeter ( mm ) measuring board with a 90 degree right angle. A meter stick is used for species over 500 mm . At each site, a sub-sample of the first 20 fish (when applicable) of each species sre measured and the remainder counted. On occasion, invertebrate species counts are estimated.
Jellyfishes, ctenophores, bryozoans, sponges, SAV and macroalgae are measured volumetrically (liters, L) using calibrated containers with small holes in the bottom to drain the excess water.

Small quantities (generally $\leq 10$ specimens) of invertebrates are occasionally counted. Slightly larger quantities of invertebrates are sometimes visually estimated. Bryozoans and macroalgae are combined for one volume measurement and a biologist estimate the percentage of each species in the sample.

Unknown species are placed in Ziploc bags on ice or kept in a bucket of water and taken to the office for identification. Rare, uncommon, and unrepresented species are fixed and preserved for the voucher collection that was started in 2006.

## Data Analysis

Statistical analyses are conducted on species that historically are most abundant in the trawl and beach seine catch data. Additional species are added to the analyses dependant on their recreational importance and biological significance as forage for adult game fish and indicators of water quality. Species rarely encountered and not considered recreationally important, including forage significance, are not included in the analyses.

The Geometric Mean (GM) is calculated to develop species specific annual trawl and beach seine indices of relative abundance (1989-2012). This method was adopted by the Atlantic States Marine Fisheries Commission (ASMFC) Striped Bass Technical Committee as the preferred index of relative abundance to model stock status. The mean is calculated using catch per area covered for trawl and catch per haul for seine. The GM is calculated from the $\log _{e}(x+1)$ transformation of the catch data and presented with 95\% Confidence Intervals (CIs; Ricker 1975). The GM and CIs are calculated as the antilog $\left[\log _{\mathrm{e}}-\mathrm{mean}(\mathrm{x}+1)\right]$ and antilog $\left[\log _{\mathrm{e}}{ }^{-}\right.$ mean $(x+1) \pm$ standard error * ( t value: $\alpha=0.05, \mathrm{n}-1)]$, respectively. A geometric grand mean was calculated for the time series (1989-2012) and used as a point estimate for comparison to the annual (2012) estimate of relative abundance.

To investigate species-specific habitat preference for finfish, an analysis of variance was performed on the catch data to determine if sites differed in mean abundance (CPUE) for each species by site for 2012. A subsequent multiple pairwise comparison of means test (Duncan’s Multiple Range Test) was performed to determine differences among sites in 2012. The site or group of sites most abundant were classified as primary sites. Secondary sites were second most abundant.

## 2012 Survey Results: Atlantic Menhaden (Brevoortia tyrannus)

Atlantic Menhaden were captured in 7 of 140 trawls (5.0\%) and in 14 of 38 beach seines (36.8\%) in 2012. A total of 2,186 Atlantic Menhaden were collected in trawl (124 fish) and beach seine (2,062 fish) samples conducted on Maryland’s Coastal Bays in 2012. Atlantic Menhaden ranked third out of 71 species in overall finfish abundance. The trawl and beach seine CPUEs were 7.1 fish/hectare and 54.3 fish/haul, respectively.

GM indices of relative abundance were calculated and compared with the 1989-2012 time series grand mean (Figures 2 and 3). The point estimate of the time series grand mean was used as an indicator of central tendency of abundance, against which the $95 \%$ CI of the GM indices of relative abundance were compared. The 2012 trawl index was below the standardized grand mean and the seine index was equal to the standardized grand mean (Figures 2 and 3). Since 1989, the trawl index occasionally (ten years) varied from the grand mean and beach seine index has varied nine times from the grand mean.

Duncan's Multiple Range Test indicated that trawl sites T005 and T006 had the highest level of abundance (CPUE) and were classified as a primary sites (Figure 1). There were no secondary trawl sites for Atlantic Menhaden. Beach seine site S 010 was determined to be a primary location and seine sites S001, S002, S003, S005, S006, S007, S008, S012, S013, S018, and S019 were classified as secondary sites (Figure 7, Table 10).

The abundance index for trawl was below the grand mean and the index for seines was equal to the grand mean. Atlantic Menhaden were caught more often in near shore locations (beach seine). Therefore, beach seine indices represent a more accurate picture of changes in relative abundance when compared to trawl indices. Significant changes in relative abundance may reflect a combination of environmental conditions (nutrient levels, water temperature, salinity, and dissolved oxygen) and/or overfishing.

The primary trawl sites were in protected areas at the head of Turville Creek (T006) and the St. Martins River (T005). Turville Creek is known to have high nutrient levels and may attract the prey sources of Atlantic Menhaden (Maryland Department of the Environment, 2001). Trawl primary sites are up at the head of creeks and are likely to have high chlorophyll concentrations, a desirable characteristic for a filter feeder (Wazniak et al. 2004). The beach seine primary site (S010) for Atlantic Menhaden was located in Grey’s creek off Sinepuxent Bay, a muddy protected bay. Primary and secondary seine sites displayed a geographically wide dispersion indicating preference for shallow water habitat with low flow characteristics.

## Virginia American Shad Monitoring Program

## Methods

Since 1998, a staked gillnet American shad monitoring program has been operating in the primary tributaries of lower Chesapeake Bay. In the James, York, and Rappahannock rivers, a single staked gillnet stand is fished on two succeeding days (two approximately 24-h sets) each week between late February and early May. Locations for each staked gillnet were based on those associated with the historic American shad logbook data, and stand locations were selected to approximate the 'average' logbook catch. The exact gear dimensions associated with the logbook data from the James and York Rivers differed slightly from those of the logbook data from the Rappahannock River. Sampling in the James and York rivers is conducted using a 273-m staked gillnet (9.1-m panel length) located at river miles $10\left(36^{\circ} 59.0^{\prime} \mathrm{N}, 76^{\circ} 28.8^{\prime} \mathrm{W}\right)$ and $14\left(37^{\circ} 20.8^{\prime} \mathrm{N}, 76^{\circ} 37.7^{\prime} \mathrm{W}\right)$, respectively (Fig. 1). In the Rappahannock River, a $277-\mathrm{m}$ staked gillnet (14.6-m panel length) is located at river mile $36\left(37^{\circ} 55.9^{\prime} \mathrm{N}, 76^{\circ} 50.4^{\prime} \mathrm{W}\right)$. Nets in the York and James Rivers are constructed of 12.4 cm stretched-mesh monofilament netting while the net used in the Rappahannock River is constructed of 12.7 cm netting.

Adult Atlantic menhaden are routinely captured as bycatch during the monitoring of American shad in all three rivers. Using these bycatch data, an index of relative abundance for Atlantic menhaden was developed using a generalized linear model (GLM). The response variable was total menhaden count and an offset variable defined to be the log of meters of net fished per day was used to account for differential effort across sampling events. Preliminary analyses supported the application of the negative binomial distribution to account for overdispersion. A total of four model parameterizations were examined and AIC statistics strongly favored the full model (Table 1). The index showed a variable pattern across years with relatively low annual estimated coefficients of variation (Fig. 2).

Table 1. Negative binomial GLM parameterizations and associated AIC fit statistics for four models applied to the menhaden bycatch data of the Virginia American shad monitoring program, 1998-2012.

| Covariates | AIC | $\Delta$ AIC |
| :---: | :---: | :---: |
| Year, Month, River | 9989.4 | 0.0 |
| Year, Month | 10001.5 | 12.1 |

# Potential Independent Data Sources for Adult Menhaden Abundance North Carolina 

## Program 135 - North Carolina Striped Bass Monitoring

## Striped Bass Independent Gill Net Survey

The objectives of the striped bass monitoring program is to monitor the status of striped bass in the Albemarle Sound/Roanoke River ( $\mathrm{A} / \mathrm{R}$ ) and the Atlantic Migratory stock to assess the effectiveness of management measures and to sustain the depressed populations of striped bass in Central/Southern North Carolina systems by stocking to help the recovery of these stocks. The stratified-random multiple-mesh Independent Gill Net Survey (IGNS) began in October of 1990 to monitor the striped bass resident and overwintering fall/winter population in the Albemarle and Croatan Sounds and the A/R striped bass spring spawning population. The 12 different mesh sizes used allow capture of fish age one and older. Sampling occurs during the fall/winter (November-February) and the spring (March-May) using multiple mesh gill nets. Mesh sizes range 2.5 to 7.0 inch square mesh (ISM) at 0.5 inch intervals, 8.0 and 10 ISM. and consist of four types of gangs- 24 forty yard gill net sections ( 960 yards fished per sampling day).

1. Large mesh floating (6.5, $5.5,7.0,6.0,8.0,10.0)$
2. Large mesh sinking (6.5, $5.5,7.0,6.0,8.0,10.0)$
3. Small mesh floating ( $2.5,3.5,4.5,3.0,4.0,5.0$ )
4. Small mesh sinking (2.5, 3.5, 4.5, 3.0, 4.0, 5.0)

There are six sample zones in Albemarle and Croatan sounds divided in one-mile square quadrants with an average of 22 quadrants per zone. (Figures 1-2).

Figure 1. Sample zones for the NCDMF striped bass fall/winter Independent Gill Net Survey, Albemarle and Croatan sounds, NC

Figure 2 Sample Zone 2 and the north/south quadrants for the NCDMF A/R striped bass spawning stock spring Independent Gill Net Survey, Albemarle Sound, NC.

Each zone is sampled once a month; with a 24 hour soak over 24 fishing days per month and a total of 96 fishing days for the fall/winter season. The spring season concentrates in western Albemarle Sound (zone 2) and is divided into southern and northern areas. Nets are fished daily 7 days a week.

Menhaden rank as the number one caught species. Only a range of FL is taken; Min-Max and total number of menhaden are recorded per sample unit. There are 30,592 lengths recorded. 261,934 total recorded number of menhaden (Figure 3). Catch per unit effort for each sampling season are in tables 1 and 2.

Figure 3 Percent length frequency of menhaden (min-max size) collected from Program 135 n=30,592.

## Program 915 -Fisheries Independent Assessment (FIA)

## Pamlico Sound Independent Gill Net Survey

This project began in March 2001 and provides fishery independent indices of relative abundance by size class, which when applied to the appropriate age-length keys can produce annual catch-at-age (CAA) estimates. These estimates will provide essential data for input into future stock assessments. Fishery independent abundance indices are needed to calibrate or tune parameter estimates and reduce uncertainty in age-based assessment techniques that rely heavily on fishery dependent data (Hilborn and Walters 1992, NRC 1998, Quinn and Deriso 1999). A long-term fishery independent database will allow the North Carolina Division of Marine Fisheries (NCDMF) to assess the status of fish stocks and track cohorts over time without relying solely on recreational and commercial fishery dependent data.

## Objectives:

1. To calculate annual indices of abundance in Pamlico Sound for the following target species: Atlantic croaker (Micropogonias undulatus), bluefish (Pomatomus saltatrix), red drum (Sciaenops ocellatus), southern flounder (Paralichthys lethostigma), spot (Leiostomus xanthurus), weakfish (Cynoscion regalis), spotted seatrout (Cynoscion nebulosus), and striped bass (Morone saxatilis).
2. To supplement samples for age, growth, and reproduction studies in order to determine age structure, sex ratios, and relative cohort size for the target species.
3. To evaluate catch rates and species distribution for identifying and resolving bycatch problems in Pamlico Sound.
4. To characterize habitat use in Pamlico Sound.

## Methods

Sampling is based on a stratified-random design by area and water depth, in two regions; Eastern Pamlico Sound, Western Pamlico Sound (Figure 4)

Figure 4. Sample regions and grid system for the Pamlico Sound Independent Gill Net Survey in Dare and Hyde counties.

Water depths are shallow ( $\leq 6$ feet) and deep ( $>6$ feet) with areas segregated into four similar size areas. Each area is sampled twice a month using stratified-random multiple mesh gill nets from February $15^{\text {th }}-$ December 15. Mesh sizes range 30 yards each (3.0, 3.5, 4.0, 4.5, 5.0, 5.5, 6.0, 6.5 ISM) 240 yards sink gill net, 12 hour soak. 480 yards fished per sampling day, 32 core samples a month ( 8 areas x twice a month x 2 samples).

## Calculation of Weighted CPUE Estimates by Size Class Distribution

Catch rates of target species are calculated annually and expressed as an overall CPUE along with corresponding length class distributions. The overall CPUE provides a relative index of abundance showing availability of each species to the study. The overall CPUE is defined as the number of a species of fish captured per sample and is further expressed as the number of a species of fish at length per sample, with a sample being one array of nets fished for 12 hours. Due to disproportionate sizes of each stratum and region, the final CPUE estimate is weighted. The total area of each region by stratum is quantified using the one-minute by one-minute grid system and then used to weight the observed catches for calculating the abundance indices. Beginning in 2005, efforts were made to increase efficiency and catch rates in deep water grids. As a result, the previous grid system (2001-2004) was modified so grids with depths not less than 9 feet and grids not located along the 6-foot bathymetric contour were eliminated. As a result the weighting factors from 2005 forward have changed from the prior period (2001-2004). The weighting factors by region and strata beginning in 2005 were:

Region 1: Shallow water - 134.5 square nautical miles
Region 1: Deep water - 54.5 square nautical miles
Region 2: Shallow water - 82.5 square nautical miles
Region 2: Deep water - 70.5 square nautical miles
In order to prevent bias due to unequal sampling across areas and time, only core samples taken each month ( $n=32$ ) are used in the calculations of the annual weighted CPUE index (Table 3).

Atlantic menhaden are the most abundant species by number. Figure 5 shows length frequencies for menhaden. Data collected include total number and weight captured, per mesh size, and a subset of 5 lengths and subsample weight per mesh size.

Figure 5. 2001-2012 Length frequency for Atlantic Menhaden in Pamlico Sound (n=133,014)

## Pamlico and Neuse Watershed Gill Net Survey and Southern District Gill net Survey

## Objectives:

1. To calculate annual indices of abundance in major North Carolina rivers for the following target species: American shad (Alosa sapidissima), Atlantic croaker (Micropogonias undulatus), bluefish (Pomatomus saltatrix), red drum (Sciaenops ocellatus), southern flounder (Paralichthys lethostigma), southern kingfish (Menticirrhus americanus), Spanish mackerel (Scomberomorus maculates), spot (Leiostomus xanthurus), spotted seatrout (Cynoscion nebulosus), striped bass (Morone saxatilis), and weakfish (Cynoscion regalis). Catch per unit effort (CPUE) data from fishery independent surveys that standardizes effort will provide an unbiased relative index of abundance to track stock status. Target species may vary by river system.
2. To supplement samples for age, growth, and reproduction studies in order to determine age structure, sex ratios, and relative cohort size for the target species.
3. To evaluate catch rates and species distribution for identifying and resolving management problems in five North Carolina river systems and the Atlantic Ocean.
4. To characterize habitat use in those five river systems.

The Pamlico, Neuse, and Pungo Rivers project began in 2003. The New and Cape Fear rivers project began in May 2008. Sampling methodology is the same as the Pamlico Sound independent gill net survey using a stratified-random design based on areas and water depth. Estuarine waters are divided into two regions: Pamlico (Pamlico, Pungo, Neuse Rivers; Figure 5) and Southern (New and Cape Fear rivers; Figure 6).

## Calculation of Weighted CPUE Estimates by Size Class Distribution

Catch rates of target species are calculated annually and expressed as an overall catch per unit effort (CPUE) along with corresponding length class distributions (Table 4 and Table 5; Figure 7 and Figure 8) . The overall CPUE gives an estimate of abundance showing availability of each species to the study, while the length distribution shows the size structure of each species for a given year. The overall CPUE is defined as the number of a species of fish captured per sample and was further expressed as the number of a species of fish at length per sample, with a sample being one array of nets. Due to disproportionate sizes of each strata and region, the final CPUE estimate is weighted. The length frequency distribution for each species is weighted by strata and number caught to determine the contribution of each size class to the final weighted CPUE. The total area of each region by strata is quantified using the one-minute by one-minute grid system and then used to weight the observed catches for calculating the abundance indices. The weighting factors by region and strata are:

Pamlico region:
Pamlico/Pungo River 1: Shallow water - 44 square nautical miles
Pamlico/Pungo River 2: Deep water - 38 square nautical miles
Neuse River 1: Shallow water - 36 square nautical miles
Neuse River 2: Deep water - 31 square nautical miles
Southern region:
New River 1: Shallow water - 12 square nautical miles
New River 2: Deep water - 12 square nautical miles
Cape Fear River: Shallow water - 14 square nautical miles

Figure 6. The sample regions and grid system for the Pamlico Region.

Atlantic menhaden are the most abundant species by number. Data collected include total number and weight captured, per mesh size, and a subset of 5 lengths and subsample weight per mesh size, fish condition (alive, dead, spoiled, alive/unmarketable).

^ In 2003 sampling in the Pamlico, Pungo, and Neuse Rivers was reinstated in July 2003 resulting in fewer samples

* In September of 2005 only half of the samples were collected resulting in 16 fewer samples

Figure 7. 2003-2012 Length frequency for Atlantic Menhaden in the Pamlico Region ( $\mathrm{n}=148,888$ )

Figure 8. Sample regions and grid system for the Southern region.
Each region is delineated into shallow ( $\leq 6$ feet) and deep ( $>6$ feet) strata. Areas in Pamlico region are segregated into four similar size areas. Areas in southern region are assigned as upper and lower New river. The Cape fear is considered one area. Each area is randomly sampled twice a month using a stratified-random multiple-mesh gill nets from February 15 - December 15. Mesh sizes range 30 yards
each (3.0, 3.5, 4.0, 4.5, 5.0, 5.5, 6.0, 6.5 ISM) 240 yards sink gill net, Soak times are 12 hour soak except from April 1 - September 31when soak times are reduced in the Cape Fear and New rivers to 3 hours to reduce interactions with sea turtles. The reduced soak times were fully implemented in 2009.

## Data

- Biological Data
- \# of individuals
- Total biomass
- Individual lengths (nearest cm)
- Total weight of all individuals
- Hydrographic Data

## \% Positive Tows by Cruise Season

| Stratum | Spring | Summer | Fall | Total |
| :--- | :---: | :---: | :---: | :---: |
| Florida | $31.58 \%$ | $26.10 \%$ | $20.94 \%$ | $26.59 \%$ |
| Georgia | $18.25 \%$ | $8.84 \%$ | $17.68 \%$ | $15.23 \%$ |
| Long Bay | $14.59 \%$ | $6.38 \%$ | $6.06 \%$ | $8.91 \%$ |
| Onslow Bay | $30.28 \%$ | $7.57 \%$ | $5.88 \%$ | $13.82 \%$ |
| Raleigh Bay | $28.10 \%$ | $5.88 \%$ | $9.23 \%$ | $13.97 \%$ |
| South Carolina | $9.09 \%$ | $2.75 \%$ | $14.38 \%$ | $8.75 \%$ |
| Avg. \% Positive | $\mathbf{2 0 . 2 1 \%}$ | $\mathbf{9 . 4 7 \%}$ | $\mathbf{1 2 . 8 1 \%}$ | $\mathbf{1 4 . 4 0 \%}$ |

## \# of Menhaden By Area and Cruise

- Highest catches during spring cruises (85.3\% of all
captured)
- Especially off GA and FL on average
- Note two exceptional catches in SC and Long Bay in 2009

## Sampling Methodology

- Sampling gear
- Electrofishing boat - ~ 3,0oo watts of pulsed direct current
- Methodology
- Near shoreline transect made with tidal current
- Shock at idle-speed approximately 1.5 to 3 m from the bank
- Targeted species
- Red drum, spotted seatrout, southern flounder, \& striped bass
- Data
- Biological
- \# of individuals and individual lengths
- Hydrographic /Sampling Data

## Methodology

- Trammel net
- 183 m long x 2.1 m deep
- Inner panel - 63.5 mm ( 2.5 in ) stretched mesh
- Outer panel - 355.6 mm ( 14 in ) stretch-mesh
- Set along the shoreline ( 10 to 20 m from an intertidal marsh flat, <2 m depth) during an ebbing tide
- Targeted species
- Red drum, spotted seatrout, southern flounder
- Data
- Biological Data
- \# of individuals and individual lengths
- Hydrographic/Sampling Data

## Size Frequency

# Atlantic Menhaden Data <br> Collected by GA DNR CRD Ecological Monitoring Trawl Survey 1995-1998, 2003-2012 

## Ecological Monitoring Trawl Survey

- Over 15,000 trawls since 1976.
- 42 monthly stations across 6 sounds (WA, OS, SP, SS, SA, Cu).
- Gear: 40 ft flat trawl net towed for 15 min.
- Monitor abundance, size, and condition of all species.
Purpose:

1) Manage shrimp and crabs
2) Provide estimates of finfish abundance

## Atlantic Menhaden Length Frequency

Spawning: Nov - Mar Offshore Larval Development: 1-3 months Dec-May
Annulli forms: Mar
Mature by $3^{\text {rd }}$ year (late Age 2) 180mm FL in SAB, 210mm in MAB

Growth is density dependent

## Atlantic Menhaden By Station

- EMTS 1995-98, 2003-2011
- CPUE = \# / standard 15 min trawl

Atlantic Menhaden by Strata 1995-2012

Strata: Character 1-Sound System, Character 2-Sector: 1=creek, 2= sound, 3=beach, 4=upriver First Character is the Sound: $1=W A, 2=O S, 4=S P, 7=S S, 8=S A, 9=C U$

Atlantic Menhaden Hydrographic Preferences 2006-2011

## Menhaden Juvenile Abundance Index Update <br> November 2011

Fishery-Independent Data - juvenile abundance index
Data collected from seine surveys conducted within several states along the east coast of the U.S. were used to develop indices of relative abundance for juvenile menhaden. The primary objective of these seine surveys is to measure the recruitment strength of species other than menhaden, that is, the underlying sampling protocols were designed to target juvenile striped bass, alosines, or other fishes and species complexes. Although menhaden are a bycatch species in these surveys, the seine catch-per-haul data represent the best available information for the construction of a menhaden juvenile abundance index (JAI).

The calculation of the menhaden JAI was based on data from the following state seine surveys:

- North Carolina alosine seine survey (1972-2010)
- Virginia striped bass seine survey (1967-1973, 1980-2010)
- Maryland striped bass seine survey (1959-2010)
- Connecticut seine survey (1987-2010)
- New Jersey seine survey (1980-2010)
- New York seine survey (1986-2010)
- Rhode Island seine survey (1988-2010)

## State seine surveys

The North Carolina Alosine seine survey (Program 100S) has operated continuously from 1972-present in the Albemarle Sound and surrounding estuarine areas. The survey targets juvenile alosine fishes and sampling is conducted monthly from June through October.

The Virginia striped bass seine survey was conducted from 1967-1973 and 1980-present. The survey targets juvenile striped bass following a fixed station design, with most sampling occurring monthly from July through September and occasional collections in October and November. In 1986 the bag seine dimensions were changed from 2 mx 30.5 $\mathrm{m} \times 6.4 \mathrm{~mm}$ to the "Maryland" style seine with the dimensions $1.2 \mathrm{~m} \times 30.5 \mathrm{~m} \times 6.4 \mathrm{~mm}$. Rivers sampled in the southern Chesapeake Bay system include the James, Mattaponi, Pamunkey, Rappahannock, and York rivers.

The Maryland striped bass seine survey targets juvenile striped bass and has operated continuously from 1954-present. Survey stations are fixed and sampled in July, August, and September with a beach seine of dimensions $1.2 \mathrm{~m} \times 30.5 \mathrm{~m} \times 6.4 \mathrm{~mm}$. Twenty-two permanent stations within the northern Chesapeake Bay system are sampled with two replicate hauls at each station in four regions: Choptank River, Head of Bay, Nanticoke River, and Potomac River.

The New Jersey striped bass seine survey targets juvenile striped bass and has operated continuously in the Delaware River from 1980-present. The sampling scheme has been modified over the years but the core survey area, sampling locations, and field time frame (June-November) have remained consistent. The current sampling protocol, which was established in 1998, consists of 32 fixed stations sampled twice a month from June through November within three distinct habitats: Area 1 - brackish tidal water; Area 2 brackish to fresh tidal water; Area 3 - tidal freshwater. A beach seine with dimensions $1.8 \mathrm{~m} \times 30.5 \mathrm{~m} \times 6.4 \mathrm{~mm}$ is used for sampling. For the menhaden juvenile index calculation, data from Area 3 were omitted due to the rare occurrences of menhaden in tidal freshwater.

The Connecticut River seine survey targets juvenile alosines in the Connecticut River and has continuously operated from 1987-present. Sampling occurs weekly from July through October with a beach seine of dimensions $2.44 \mathrm{~m} \times 15.2 \mathrm{mx} 0.5 \mathrm{~cm}$. Approximately 56 hauls are taken annually from four sites in the lower River located at Deep River, Essex, Glastonbury, and mouth of the Salmon River.

The Rhode Island seine survey targets a variety of fishes in Narragansett Bay and has operated continuously from 1988-present. The survey began with 15 stations in 1988 increasing by one station in each year of 1990, 1993, and 1995, for a total of 18 fixed stations. All 18 fixed stations are sampled in each month from June through October using a beach seine with dimensions $3.05 \mathrm{~m} \times 61 \mathrm{~m}$ with mesh size running from 0.635 cm in the wings to 0.476 cm in the bunt.

The New York seine survey targets a variety of fishes in western Long Island Sound and has operated continuously from 1984-present. Sampling occurs with a 61 m beach seine primarily from May through October within three areas: Jamaica Bay, Little Neck Bay, and Manhasset Bay.

## Potential biases

Because of the schooling nature of Atlantic menhaden combined with the fact that these seine surveys were originally designed to measure the abundance of other species, it is possible that the menhaden catch data are not truly representative abundance.

## Biological Sampling

Length data (in mm) were available for the seine surveys conducted by North Carolina, Virginia, Maryland, and New Jersey; little or no length data are available for the seine surveys conducted by Connecticut, and Rhode Island.

## Aging Methods

For state seine surveys (North Carolina, Virginia, Maryland, New Jersey, and New York) with length data, catch-per-haul data were adjusted based on the convention cut-off sizes by month for juvenile menhaden adopted by the Atlantic menhaden Technical Committee in March 2003. Juvenile length cutoffs were defined as: June 1-June 30, 110 mm FL; July 1-August 15, 125 mm FL; and August 16-November 30, 150 mm FL.

## Coastwide Index

A coastwide index of juvenile menhaden abundance was developed by combining the state-specific seine data into a single dataset. As noted in the most recent menhaden stock assessment, examination of the raw catch-per-haul data for each state indicated that each data set contained a high proportion of zero catches, or alternatively, a low proportion of hauls where at least one juvenile menhaden was captured (ASMFC 2010). Zero catches can arise for many reasons, and it was reasoned that the use of an active sampling gear combined with the schooling nature of menhaden was the likely cause (Maunder and Punt 2004). Although a variety of strategies can be used to deal with zero catches, in the most recent stock assessment a delta approach was adopted where the probability of obtaining a zero catch and the catch rate, given that the catch is non-zero, were modeled separately (Maunder and Punt 2004). The general form of a delta model is:

$$
\operatorname{Pr}(Y=y)= \begin{cases}w & y=0 \\ (1-w) f(y) & \text { otherwise }\end{cases}
$$

Based on analyses described in the most recent assessment report, the probability of obtaining a zero observation was modeled using the binomial distribution and the distribution used to model the non-zero catches was assumed to be lognormal (ASMFC 2010). The delta-lognormal GLM used to develop the coastwide juvenile relative abundance index included year, month, and state as fixed factors. All statistical analyses were conducted using the software package R, version 2.11.0 (R Development Core Team, 2010).

## State-Specific Indices

Indices of relative menhaden juvenile abundance were also developed for each state separately. A delta-lognormal GLM that included year and month as fixed factors was fitted to the state-specific data.

The index trends from the late 1990s through the mid 2000s are generally variable but higher in more northerly states when compared to the more southerly states (Figure 2). The 2009 and 2010 index years are either roughly the same or lower than previous years for all states except Virginia. The Virginia index values for those years are the highest when compared to the previous 15 years.

## Results

The trend of the coastwide index is generally low during the 1960s, high from the mid 1970s to mid 1980s, and low to moderate from the mid 1980s to the present (Figure 1). Over the past 20 years, noteworthy strong year-classes occurred in 1999 and 2005.

The state-specific index trends from the late 1990s through the mid 2000s are generally variable but higher in more northerly states when compared to the more southerly states (Figure 2). The 2009 and 2010 index years are either roughly the same or lower than previous years for all states except Virginia.

Correlation analysis indicates strong correlation ( $\mathrm{r}>0.65$ ) between the coastwide index and the four most southern state indices (NC, VA, MD, NJ). In comparison, NY, CT, and RI had Pearson correlation coefficients of 0.35 or less. Although recruitment from all areas is important, the strong influence of the southern state indices on the coastwide index corresponds well with the general understanding that the Chesapeake Bay region is the epicenter of menhaden recruitment (J. Smith, personal communication).

The Virginia index values for 2009 and 2010 are the highest values in nearly two decades for that survey. Strong recruitment in this region in recent years is corroborated by an increase in the percentage of age-1 individuals in the Chesapeake Bay harvest.
