## MEMORANDUM

April 22, 2015

## To: Atlantic Menhaden Management Board <br> From: Atlantic Menhaden Technical Committee <br> RE: Recommended Biological Reference Points and Projection Runs

## Biological Reference Points

After consideration of the recommendations from the 2015 Atlantic Menhaden Benchmark Stock Assessment Peer Review Panel, the Technical Committee (TC) recommends that the biological reference points for the Atlantic menhaden population be based on MSP (maximum spawning potential). The percentages should be determined from the minimum and median values of MSP during the time frame 1960-2012, a period during which the TC considers the population to have been sustainably fished. These reference points are therefore based on the historical performance of the population given the fishing pressure that the population has experienced.

As recommended by the Peer Review Panel, and accepted by the TC, the value for fishing mortality reference points will be the geometric mean of fishing mortality on ages-2 to -4 . These ages represent the fully selected fishing mortality rates depending upon the year and fishery (i.e., bait and reduction). The fecundity (FEC) reference points match the F reference points meaning they are equal to the fecundity estimated when $F$ reaches equilibrium at its target and threshold MSP levels, respectively. Under these reference points, the stock status is not overfished and overfishing is not occurring (Table 1; Figures 1 and 2). In addition, Monte Carlo bootstrapping (MCB) runs corroborates the assessment finding that the stock status is not overfished and overfishing is not occurring.

Table 1. Biological Reference Points from the 2015 Benchmark Stock Assessment as recommended by the Peer Review Panel and TC. The table also contains the terminal year estimate of F, and FEC (in billions of eggs).

| Reference Points/Terminal Year Estimate | Benchmark |
| :--- | :---: |
| $\mathrm{F}_{26 \% \text { MSP }}$ (threshold) | 1.26 |
| F $_{57 \% \text { MSP }}$ (target) | 0.38 |
| F $_{70 \% \text { MSP }}$ (F in 2013) | 0.22 |
| FEC $_{26 \% \text { MSP }}$ (threshold) | 86,821 |
| FEC $_{57 \% \text { MSP }}$ (target) | 189,270 |
| FEC $_{2013}$ (FEC in 2013) | 170,536 |

## Projections

MCB of the base run of the Beaufort Assessment Model (BAM) was used as the basis for the projections (see Appendix D of 2015 assessment for projection methodology). Projections were run for four years (2014-2017). The duration of projections was short-term in order to maintain at least one age class present in the terminal year of the assessment within the projections.

Landings in 2014 were the same in all runs and were assumed to be 170,800 mt (the 2014 TAC) because final landings data were not available at the time of the projection analysis. Constant landings from 2015 to 2017 were allocated to the bait and reduction fishery in the northern and southern regions using the proportions established in Amendment 2.

The TC explored seven separate projection runs to account for the range of projections requested by the Board. The projections explore a range of TAC levels from status quo to catch levels that existed prior to the implementation of Amendment 2 . Specifically, projections were run using the following TAC scenarios:

1) $213,500 \mathrm{mt}=$ average catch from 2009-2011 prior to implementation of Amendment 2
2) $202,825 \mathrm{mt}=$ if Board had implemented a $5 \%$ reduction from 2009-2011 average catch
3) $192,150 \mathrm{mt}=$ if Board had implemented a $10 \%$ reduction from 2009-2011 average catch
4) $181,475 \mathrm{mt}=$ if Board had implemented a $15 \%$ reduction from 2009-2011 average catch
5) $170,800 \mathrm{mt}=2014 \mathrm{TAC}$ (status quo; Amend 2 implemented $20 \%$ reduction from 2009-2011 average catch)
6) TAC that has a $50 \%$ probability of achieving F target in 2017 (constant catch approach)
7) TAC that has a $50 \%$ probability of achieving $F$ target in every year (constant $F$ approach)

No guidance on risk policy was provided by the Management Board for the projection runs that estimate TACs that achieve F target. Therefore, the TC applied a 50\% probability of achieving F target as a default.

## Projections 1-5

Results in the table below indicate a percent risk of exceeding the $\mathrm{F}_{\text {target }}$ (Table 2) or the Fthreshold (Table 3) under the various projected TAC levels that would be held constant for a three year time period (2015-2017). The probability of exceeding the F target decreases over time because of the recruitment assumptions within the projections (median recruitment with variability based on historical recruitment). This means that using median recruitment with historical variability ultimately results in higher levels of recruitment in the projections than recently observed.

Table 2. Percent risk of exceeding the $\mathrm{F}_{\text {target }}$ for a given TAC scenario.

|  | TAC (mt) | $\mathbf{2 0 1 5}$ | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 7}$ |
| :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{1 7 0 , 8 0 0}$ | $50 \%$ | $23 \%$ | $3 \%$ |
| Percent Risk | 181,475 | $57 \%$ | $28 \%$ | $9 \%$ |
| of exceeding | 192,150 | $62 \%$ | $35.5 \%$ | $15 \%$ |
| Ftarget | 202,825 | $68 \%$ | $42 \%$ | $21.5 \%$ |
|  | 213,500 | $73 \%$ | $49.5 \%$ | $27.5 \%$ |

Table 3. Percent risk of exceeding the Fthreshold for a given TAC scenario.

|  | TAC (mt) | $\mathbf{2 0 1 5}$ | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 7}$ |
| :---: | :---: | :---: | :---: | :---: |
| Percent Risk | 170,800 | $1.5 \%$ | $0 \%$ | $0 \%$ |
| of exceeding | 181,475 | $2 \%$ | $0 \%$ | $0 \%$ |
| Fthreshold | 192,150 | $2 \%$ | $0 \%$ | $0 \%$ |
| (Overfishing) | 202,825 | $3 \%$ | $<0.5 \%$ | $0 \%$ |
|  | 213,500 | $4 \%$ | $<1 \%$ | $0 \%$ |

## Projection 6

The TAC that has a 50\% probability of achieving F target in 2017 (constant catch approach) was 246,900 mt (Table 4).

Table 4. Percent risk of a $246,900 \mathrm{mt}$ TAC exceeding Ftarget or Fthreshold. TAC would be held constant for a three year time period (2015-2017).

|  | $\mathbf{2 0 1 5}$ | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 7}$ |
| :--- | :---: | :---: | :---: |
| Percent risk of exceeding Ftarget | $84 \%$ | $72 \%$ | $50 \%$ |
| Percent Risk of exceeding Fthreshold | $8.5 \%$ | $<1 \%$ | $0 \%$ |

## Projection 7

TAC that has a $50 \%$ probability of achieving $\mathrm{F}_{\text {target }}$ in every year (constant F approach; Table 5). Note the TAC would change each year to ensure a $50 \%$ probability of maintaining F at the target.

Table 5. Percent risk of TAC exceeding Ftarget or Fthreshold for the constant F scenario.

|  | $\mathbf{2 0 1 5}$ | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 7}$ |
| :--- | :---: | :---: | :---: |
| TAC (mt) | 173,000 | 223,900 | 265,900 |
| Percent risk of exceeding Ftarget | $50 \%$ | $50 \%$ | $50 \%$ |
| Percent Risk of exceeding Fthreshold | $1.5 \%$ | $0 \%$ | $0 \%$ |

Figures 3-9 show panels of fecundity, recruits, fishing mortality, and landings for each TAC scenario.

Tables 6 and 7 show the allocation of the different projection run TACs by state/jurisdiction using Amendment 2 allocation.

## Uncertainty in Projections

Projections should be interpreted in light of the model assumptions and key aspects of the data. Some major considerations are the following:

- In general, projections of fish stocks are highly uncertain, particularly over the long-term (e.g., beyond five years).
- Although projections included many major sources of uncertainty, they did not include structural (model) uncertainty. That is, projection results are conditional on one set of functional forms used to describe population dynamics, selectivity, recruitment, etc.
- Fisheries were assumed to continue fishing at their estimated current proportions of total effort (for bait and reduction fisheries), using the estimated current selectivity patterns. New management regulations that alter those proportions or selectivities would likely affect projection results.
- All of the projections assume median recruitment over time. So if future recruitment is characterized by runs of large or small year classes, possibly due to environmental or ecological conditions, stock trajectories may be affected.
- Projections apply the Baranov catch equation to relate F and landings using a one-year time step, as in the assessment. The catch equation implicitly assumes that mortality occurs throughout the year. This assumption is violated when seasonal closures are in effect, introducing additional and unquantified uncertainty into the projection results.

Table 6. Allocation (in pounds) to states/jurisdiction under the different potential TAC scenarios using Amendment 2 allocation after $1 \%$ of the TAC has been set aside for Episodic Events. This table contains potential TACs associated with the constant harvest projection runs 1 through 6 .

## Figures

Figure 1. The geometric mean fishing mortality rate of ages-2 to -4 versus the recommended fishing mortality reference points with the blue line as the threshold and the orange line as target.

Figure 2. The fecundity versus the recommended fecundity based reference points with the blue line as the threshold and the orange line as the target.

Figure 3. Projection panels for $170,800 \mathrm{mt} \mathrm{TAC}$. Fecundity, recruits, geometric mean fishing mortality ( $F$ ) over ages-2 to -4 , and landings over time based on constant landings and median recruitment with variability based on estimated deviations for each MCB run. The solid flat line in the landings panel is the constant landings specified in the model ( $170,800 \mathrm{mt}$ ). The solid flat lines in the fishing mortality rate and fecundity panels are the threshold (blue) and target (orange) benchmark values recommended by the TC from the base run.

Year

Figure 4. Projection panels for $181,475 \mathrm{mt} \mathrm{TAC}$. Fecundity, recruits, geometric mean fishing mortality $(F)$ over ages- 2 to -4 , and landings over time based on constant landings and median recruitment with variability based on estimated deviations for each MCB run. The solid flat line in the landings panel is the constant landings specified in the model ( $181,475 \mathrm{mt}$ ). The solid flat lines in the fishing mortality rate and fecundity panels are the threshold (blue) and target (orange) benchmark values recommended by the TC from the base run.

Figure 5. Projection panels for $192,150 \mathrm{mt} \mathrm{TAC}$. Fecundity, recruits, geometric mean fishing mortality $(F)$ over ages-2 to -4 , and landings over time based on constant landings and median recruitment with variability based on estimated deviations for each MCB run. The solid flat line in the landings panel is the constant landings specified in the model ( $192,150 \mathrm{mt}$ ). The solid flat lines in the fishing mortality rate and fecundity panels are the threshold (blue) and target (orange) benchmark values recommended by the TC from the base run.

Figure 6. Projection panels for $202,825 \mathrm{mt} \mathrm{TAC}$. Fecundity, recruits, geometric mean fishing mortality ( $F$ ) over ages-2 to -4 , and landings over time based on constant landings and median recruitment with variability based on estimated deviations for each MCB run. The solid flat line in the landings panel is the constant landings specified in the model ( $202,825 \mathrm{mt}$ ). The solid flat lines in the fishing mortality rate and fecundity panels are the threshold (blue) and target (orange) benchmark values recommended by the TC from the base run.

Figure 7. Projection panels for $213,500 \mathrm{mt} \mathrm{TAC}$. Fecundity, recruits, geometric mean fishing mortality ( $F$ ) over ages-2 to -4 , and landings over time based on constant landings and median recruitment with variability based on estimated deviations for each MCB run. The solid flat line in the landings panel is the constant landings specified in the model ( $213,500 \mathrm{mt}$ ). The solid flat lines in the fishing mortality rate and fecundity panels are the threshold (blue) and target (orange) benchmark values recommended by the TC from the base run.

Figure 8. Projection panels for $246,900 \mathrm{mt} \mathrm{TAC}$. Fecundity, recruits, geometric mean fishing mortality ( $F$ ) over ages-2 to -4 , and landings over time based on median recruitment with variability based on estimated deviations for each MCB run. The orange line in the fishing mortality rate panel is the target rate of 0.38 , and the blue line in the fishing mortality rate panel is the threshold rate of 1.26. The orange line in the fecundity panel is the target value, while the blue line in the fecundity panel is the threshold value. The landings values are constant at $246,900 \mathrm{mt}$ with a $50 \%$ probability of achieving F target in 2017.

Figure 9. Projection panels for constant F scenario. Fecundity, recruits, geometric mean fishing mortality $(F)$ over ages-2 to -4 , and landings over time based on median recruitment with variability based on estimated deviations for each MCB run. The orange line in the fishing mortality rate panel is the target rate of 0.38 , and the blue line in the fishing mortality rate panel is the threshold rate of 1.26. The orange line in the fecundity panel is the target value, while the blue line in the fecundity panel is the threshold value. The TAC changes each year to maintain a $50 \%$ probability of F being at F target.
