## I. Status of the Fishery Management Plan

The Atlantic States Marine Fisheries Commission (Commission) adopted its first Fishery Management Plan (FMP) for Weakfish in 1985. Amendment 1 to the FMP (1992) unsuccessfully aimed to improve the status of weakfish. Amendment 2 (1995) resulted in some improvement to the stock, but several signs indicated that further improvement was necessary. Thus, Amendment 3 (1996) was implemented to increase the sustainability of the fishery. Addendum I to Amendment 3 was approved in 2000 in order to extend the management program until the next amendment was implemented.

Amendment 4 was approved in 2002. The goal of Amendment 4 is to utilize interstate management so that Atlantic coastal weakfish recover to healthy levels that will maintain commercial and recreational harvest consistent with a self-sustaining spawning stock and to provide for restoration and maintenance of essential habitat (ASMFC 2002). The management objectives are to:

1) establish and maintain an overfishing definition that includes target and threshold fishing mortality rates and a threshold spawning stock biomass to prevent overfishing and maintain a sustainable weakfish population;
2) restore the weakfish age and size structure to that necessary for the restoration of the fishery;
3) return weakfish to their previous geographic range;
4) achieve compatible and equitable management measures among jurisdictions throughout the fishery management unit, including states' waters and the federal EEZ;
5) promote cooperative interstate research, monitoring, and law enforcement necessary to support management of weakfish;
6) promote identification and conservation of habitat essential for the long term stability in the population of weakfish; and
7) establish standards and procedures for both the implementation of Amendment 4 and for determination of states' compliance with provisions of the management plan.

Amendment 4 established target and threshold fishing mortality rates and a threshold spawning stock biomass level to determine overfishing and overfished stock status. The amendment requires states to implement recreational and commercial management measures to achieve annual fishing mortality targets. Some management measures are specified (e.g., minimum size limit, minimum mesh size, bycatch limit), while the amendment provides the states flexibility in implementing other regulations (e.g., trip limits, area or season closures). States may request implementation of alternative management plans with conservationally equivalent measures. States deemed to have insignificant landings were exempt from the recreational and commercial requirements, with the exception of the bycatch reduction devise requirements.

The Commission adopted Addendum I to Amendment 4 (2005) to replace the biological sampling program in section 3.0 of Amendment 4. In response to a significant decline in stock abundance and increasing total mortality since 1999, the Commission approved Addendum II to Amendment 4 (2007) to reduce the recreational creel limit and commercial bycatch limit, and set landings levels that when met will trigger a re-evaluation of management measures. Addendum III to Amendment 4 (2007) altered the bycatch reduction device certification requirements in Section 4.2.8 of Amendment 4 for consistency with the South Atlantic Fishery Management Council's Shrimp FMP. The Commission approved Addendum IV to Amendment 4 in 2009 to
respond to the results of the 2009 benchmark stock assessment (additional information is provided in Section VI. Status of Management Measures and Issues).

Weakfish are managed under this plan as a single stock throughout their coastal range. All Atlantic coast states from Massachusetts through Florida and the Potomac River Fisheries Commission have a declared interest in weakfish. See Table 1 for a summary of state-by-state regulations in 2012.

## II. Status of the Stock (see also Appendix A)

The weakfish stock is depleted and overfishing is not occurring (NEFSC 2009a, NEFSC 2009b). In general, weakfish biomass has declined to an all time low, total mortality is currently high, and non-fishing mortality has increased in recent years. While overfishing has not occurred in recent years, harvest was reduced by an estimated $60 \%$ in Addendum IV to reduce additional mortality from fishing and poise the stock for a quicker recovery should natural mortality decline.

Between 1982 and 1990, age $1+$ weakfish biomass ${ }^{1}$ declined drastically from 113.1 million pounds to 17.6 million pounds (Figure 1). Overfishing was the main cause of this decline, with fishing mortality ( F ) accounting for about $60-90 \%$ of total mortality (fishing plus natural mortality) during the period. Fishing mortality ${ }^{2}$ peaked at 1.01 in 1989, but with the implementation of management measures in the early to mid-1990s, F declined to 0.24 in 1995 and biomass responded favorably by increasing to a peak of 62.1 million pounds in 1996 (Figure 1). While F remained relatively stable (between 0.26 and 0.58 ) after that time, the stock began another drastic decline in 2001 to the time-series low of 10.8 million pounds in 2008. However, the contribution of fishing mortality to total mortality was substantially reduced during this period; from 2004-2007 only 10-20\% of total mortality is attributed to fishing mortality. Conversely, natural mortality has risen substantially since 1995 (Figure 1), and factors such as predation, competition, and changes in the environment are thus believed to be having a stronger influence on recent weakfish stock dynamics than fishing mortality. Bycatch and under-reported catches would have to be much greater than those estimated, growing from about 3-4 times the estimates in 1996 to $15-20$ times in the most recent years, to account for the biomass decline. Thus far, there is no evidence available of an Atlantic coast fishery capable of generating additional unreported weakfish discards of this magnitude.

Currently, the stock's spawning potential is considered to be at only $4 \%$ of an unfished stock, well below the $20 \%$ spawning potential threshold and $30 \%$ spawning potential target adopted in Addendum IV. Trends in F indicate a stable and modest fishing mortality. Thus, while the stock biomass is depleted, overfishing is not occurring.

## III. Status of the Fishery

At 539,318 pounds, the total coastwide landings of weakfish in 2012 are a drastic increase from the lowest-on-record landings from $2011(160,542 \mathrm{lbs})$. Total landings are still well below the ten-year (2002-2011) average of 2.0 million pounds. The commercial fishery $(273,606)$

[^0]accounted for $51 \%$ of the total 2012 landings, and the recreational fishery ( $265,712 \mathrm{lbs}$ ) for $49 \%$ (Table 2).

## Commercial Fishery

Commercial data are cooperatively collected and compiled by the National Marine Fisheries Service (NMFS) and state fishery agencies from state mandated trip-tickets, landing weigh-out reports from seafood dealers, federal logbooks, shipboard and portside interviews, and biological sampling of catches. Landings from the NMFS Fisheries Statistics Division are used within this report unless a state reports alternative values in its compliance report to the Commission, in which case these values are used (see notes for Table 3).

Between 1982 and 2012, coastwide commercial weakfish landings have ranged from the high of 21.1 million pounds in 1986 to the low of 133,085 pounds in 2011 (Table 3). Since 1988, the overall trend is declining except for during the period of 1990-1998 when landings hovered between 6.1 and 9.1 million pounds (Figure 2). Landings in 2012 were 273,606 pounds.

North Carolina ( 33 \%) and New York ( 22 \%) landed the largest shares of the 2012 coastwide commercial weakfish landings (Figure 3). Some states (FL, GA, PRFC, DE, CT, RI, MA) reported increases in landings since 2011, but that is only because recent landings are very low, so in comparison the increased landings are not significant (Table 3).

The dominant commercial gears in 2012 were gill nets (about $35 \%$ of the total commercial landings, respectively; NMFS 2012). There has been a shift in the dominant source of landings from trawls in the 1950s-1980s to gill nets in the 1990s-present. The majority of commercial landings tend to occur in the fall and winter months, presumably as the fish congregate to migrate to over-wintering grounds in the South Atlantic (Hogarth et al. 1995).

## Recreational Fishery

Recreational catch statistics are collected by the NMFS. Effort data are collected through telephone interviews. Catch expansions are based on angler interviews and biological sampling conducted by trained interviewers stationed at fishing access sites. All recreational data in this report are from the NMFS Fisheries Statistics Division queried from the Marine Recreational Information Program (MRIP; 2012), except as noted in section VI of this report for Florida's estimates.

Since 1982, coastwide recreational landings have ranged from the high of 11.4 million pounds in 1983 to the low of 27,436 pounds in 2011 (Table 4). Landings averaged 7.8 million pounds from 1982-1988, before falling to 2.1 million pounds in 1989. Annual recreational landings generally fluctuated between one and four million pounds from 1990 to 2002, before dropping below one million pounds in 2003 (Figure 2). Landings have averaged 307 thousand pounds (or 238 thousand fish) the last five years (Table 5), and are estimated at 265,712 pounds ( 216,474 fish) in 2012. The number of fish released alive by anglers remained above 1 million fish from 1992 to 2008, peaked at over 5 million in 1996, decreased to 1.2 million fish in 2012 (Table 6, Figure 4).

New Jersey anglers have consistently harvested the most weakfish by pounds along the coast. In the 1980s and 1990s, anglers in Delaware, Maryland, and Virginia often took the next largest shares of the recreational total amount. In the 2000s, New Jersey anglers led in the harvest, whereas anglers in Virginia and North Carolina tended to take the second and third largest
amounts (Tables 4 and 5). However, from 2009-2011, North Carolina anglers landed the largest share while South Carolina and Virginia had the next largest shares of the recreational harvest. This trend appears to have ended though, as New Jersey harvested the most fish (by pounds) in 2012. More specifically, New Jersey had $59 \%$ of the of the coastwide harvest, followed by North Carolina anglers with $17 \%$ (by pounds; Figure 5).

The recreational fishery catches weakfish using live or cut bait, jigging, trolling, and chumming. The majority of recreationally harvested weakfish are caught in state waters ( $85.5 \%$ in 2012 by pounds). In 2011, nearly all recreationally harvested fish were caught from private or rental boats ( $43 \%$ ) or from shore ( $53 \%$ ).

## IV. Status of Assessment Advice

An assessment was completed in 2009 by the Weakfish Stock Assessment Subcommittee (NEFSC 2009a, NEFSC 2009b) and peer reviewed by the $48^{\text {th }}$ Stock Assessment Review Committee (Sullivan et al. 2009) at the $48^{\text {th }}$ Northeast Regional Stock Assessment Workshop (SAW). The assessment includes fishery data and survey indices through 2007.

As recommended by previous review panels, an age-structured VPA was used to evaluate trends in population parameters. This model provided reasonable estimates of fishing mortality and biomass from 1981-2001 with estimates converging regardless of the terminal year of the model; however, estimates from 2002 onward were subject to excessive bias when adding additional years of data, making them unusable for analysis. An alternative approach using an index-based model (where relative values are estimated from harvest and survey data and then scaled to absolute values based on results from the early, more stable part of the VPA time series) was developed. Two surplus production models were also included in the assessment because these could include additional sources of mortality, such as predation, competition, and environmental factors. The peer review panel endorsed using, on an interim basis, the index-based model for estimating biomass and fishing mortality, weakfish relative spawning stock biomass projections, and a biomass threshold approximating $20 \%$ of unfished SSB. The review panel recommended that the SAS develop additional methods to analyze the stocks in the next assessment.

## V. Status of Research and Monitoring

## Fishery-Independent Data

Young-of-year indices of relative abundance are provided by Rhode Island, Connecticut, New York, New Jersey, Delaware, Maryland, Virginia, North Carolina, and Florida. Connecticut, New Jersey, Delaware, North Carolina, Georgia, and Florida provide age-0+ or 1+ indices of relative abundance. The Northeast Fisheries Science Survey Groundfish Trawl Survey also produces an age-structured index for the Mid-Atlantic coast, while the Southeast Area Monitoring and Assessment Program (SEAMAP) survey produces another for the South Atlantic Coast. The Northeast Area Monitoring and Assessment Program (NEAMAP) began spring and fall surveys between Martha's Vineyard and Cape Hatteras in the fall of 2007, and will provide an index in the future. The Chesapeake Bay Multispecies Monitoring and Assessment Program (ChesMMAP), which began in 2002, collects data on relative abundance, length, weight, age, sex, and trophic interactions in the Bay. See Table 9 for the indices provided in the 2012 compliance reports.

## Fishery-Dependent Data

The coastal states and the NMFS collect data on commercial and recreational landings. Addendum I to Amendment 4 requires the collection of otoliths and lengths to characterize the catch; the number of samples required is based on the magnitude of each state's fisheries. Each spring, the states are required to submit biological sampling plans, and each fall, through the compliance reports, the states are required to provide the actual sampling levels completed. See Section VII for more information.

## VI. Status of Management Measures and Issues

## Fishery Management Plan

Addendum IV to Amendment 4 was approved in November 2009, and was implemented in May 2010. In response to the 2009 stock assessment results, the addendum implements more appropriate biological reference points in response to recent stock dynamics and reduces harvest while attempting to minimize unnecessary bycatch waste, thus poising the stock for recovery should natural mortality decrease. Addendum IV requires all states in the management unit (including those that are de minimis) to implement a recreational creel limit no greater than 1 fish, commercial trip and bycatch limits no greater than 100 pounds, and a finfish trawl fishery allowance for up to 100 undersized fish. The addendum adopted percentage based biological reference points with an overfished/depleted threshold of $20 \%$ SSB and a target of $30 \%$ SSB. The biological sampling requirements under Addendum I are unchanged, and all regulations previously enacted to protect weakfish and reduce bycatch are to remain effective.

No additional amendments or addenda are under development.

## Florida Management Area and Landings Data

In November 2009, the Management Board approved a proposal from Florida to reduce the state's weakfish management area to a small area in northeast Florida where pure weakfish are known to occur based on genetics data. The revision is intended to address the misidentification of weakfish, sand seatrout, and their hybrids, and the consequential law enforcement issue. Inside the newly established weakfish management area (St. Mary's River only), any fish that resembles weakfish will be considered weakfish for enforcement purposes, both for commercial and recreational limits. Outside the weakfish management area, all fish that resemble weakfish will be considered sand seatrout.

As a result of the approved proposal, the commercial and recreational landings data provided in Florida's 2012 compliance report represent the best estimate of pure weakfish landings in the state. Commercial landings data from Florida's trip ticket program and recreational landings from the NMFS's Marine Recreational Fisheries Statistics Survey include only weakfish landed in Nassau and Duval counties, as revised on the basis of the genome proportions within the Cynoscion-complex found in the counties ( $48 \%$ weakfish in Nassau County and 17\% in Duval County). The landings tables and figures in this report use the landings as reported by Florida.

## De Minimis Status

Amendment 4 permits states to request de minimis status if, for the last two years, their combined average commercial and recreational landings (by weight) constitute less than $1 \%$ of the
coastwide commercial and recreational landings for the same two year period. The de minimis threshold for 2012, calculated with 2011 and 2012 harvest data, is 4,040 pounds.

Four states requested de minimis status in their 2012 compliance reports: Florida, Georgia, Connecticut, and Massachusetts. Each of these states has had a previous de minimis request approved and qualify for de minimis status (Florida $0.17 \%$, Georgia 0.41 , Connecticut $0.37 \%$, and Massachusetts $0.09 \%$ ). If any de minimis state were to lose its designation as such, the state would be required to implement the regulatory and monitoring requirements from which it was previously exempt.

## Addendum II Management Triggers

In 2010, the recreational and commercial management measures in Addendum IV replaced those in Addendum II. However, the Plan Review Team will continue to include an evaluation of the two management triggers as they provide perspective on the magnitude of fishery landings (but hitting a trigger will not require Board reconsideration of the management measures).

Addendum II established two management triggers that would require the Board to consider modifying management measures if reached. First, commercial management measures are to be re-evaluated if coastwide commercial landings exceed $80 \%$ of the mean commercial landings from 2000-2004, or 2.99 million pounds. Second, commercial and recreational management measures are to be re-evaluated if any single state's landings exceed its five-year mean by more than $25 \%$ in any single year.

The 2012 coastwide commercial landings are 273,606 pounds, thus the first trigger has not been exceeded. The second trigger was met in six states because their landings increased by more than $25 \%$ in any single year, however, this drastic increase is due to extremely low landings in previous years and is not cause for concern (Table 7).

## VII. Implementation of FMP Compliance Requirements for 2012

Mandatory compliance elements for 2012 were provided by Amendment 4 and its three addenda.

## Regulatory Requirements

The management program includes regulatory requirements for non de minimis states as follows:

- Recreational management measures including maximum creel limits and minimum size limits (see Addendum II to Amendment 4)
- Commercial management measures including minimum size limits, minimum mesh size limits, trip limits, bycatch limits, closed seasons and areas, and bycatch reduction device requirements (see Section 4.2 of Amendment 4, and Addendum II)

The PRT finds all states to have implemented the plan's compliance requirements.
See Table 1 for a summary of state commercial and recreational regulations in 2012.

## Monitoring Requirements

Addendum I implemented monitoring requirements for non de minimis states as follows:

- Maintenance of at least the 2005 level of recreational sampling of individual lengths through the Marine Recreational Fisheries Statistics Survey;
- Collection of six individual fish lengths for each metric ton of weakfish landed commercially;
- Collection of three individual fish ages for each metric ton of total weakfish landed, with a maximum of 1000 ages annually per state.

Table 8 provides the otolith and length collection requirements for 2011. These are based on the best available 2011 landings data provided to the Commission by the NMFS and the states. Table 8 also provides the number of otoliths and lengths collected by the states in 2012.

## VIII. Recommendations of the Plan Review Team

## Management Recommendations

- That the Board consider the de minimis requests from Massachusetts, Connecticut, Georgia, and Florida.
- That the Technical Committee and Stock Assessment Subcommittee explore alternative assessment methods for the next benchmark stock assessment and continue to compile the input data for the interim assessment model should an update assessment be requested prior to the next benchmark assessment.

## Research Recommendations

## Fishery-Dependent Priorities <br> High

- Increase observer coverage to identify the magnitude of discards for all commercial gear types from both directed and non-directed fisheries. ${ }^{1}$

## Moderate

- Continue studies on temperature, size, and depth specific recreational hook and release mortality rates, particularly catches from warm, deep waters. Investigate methods to increase survival of released fish.
- Continue studies on mesh size selectivity, particularly trawl fisheries. ${ }^{2}$

Low

- Determine the onshore versus offshore components of the weakfish fishery.
- Collect catch and effort data including size and age composition of the catch, determine stock mortality throughout the range, and define gear characteristics. In particular, increase length frequency sampling in fisheries from Maryland and further north.
- Develop latitudinal, seasonal, and gear specific age length keys coast wide. Increase sample sizes for gear specific keys.

## Modeling / Quantitative Priorities

High

- Evaluate predation of weakfish with a more advanced multispecies model (e.g., the ASMFC MSVPA or Ecopath with Ecosim) to validate estimates calculated by production models with predation-competition extensions.
- Develop a bioenergetics model that encompasses a broader range of ages than Hartman and Brandt (1995) and use it to evaluate diet and growth data.
- Analyze the spawner-recruit relationship and examine the effects of the relationship between adult stock size and environmental factors on year class strength.
- Quantify trawl bycatch. Refine estimates of discard mortality based on factors such as distance from shore and other geographical differences for all sizes including below minimum size.

## Life History, Biological, and Habitat Priorities <br> High

- Develop a coast wide tagging program to identify stocks and determine migration, stock mixing, and characteristics of stocks in over wintering grounds. Determine the relationship between migratory aspects and the observed trend in weight at age. ${ }^{3}$
- Monitor weakfish diets over a broad regional and spatial scale.

## Moderate

- Identify and delineate weakfish spawning habitat locations and environmental preferences to quantify spawning habitat.
- Compile data on larval and juvenile distribution from existing databases to obtain preliminary indications of spawning and nursery habitat location and extant.
- Examine geographical and temporal differences in growth rate (length and weight at age).

Low

- Determine the impact of power plants and other water intakes on larval, post larval, and juvenile weakfish mortality in spawning and nursery areas. Calculate the resulting impact on adult stock size. ${ }^{4}$

## Management, Law Enforcement, and Socioeconomic Priorities

Moderate

- Assemble socioeconomic data as it becomes available from ACCSP.

Low

- Define restrictions necessary for implementation of projects in spawning and over wintering areas and develop policies on limiting development projects seasonally or spatially.

Notes: FL: state-reported landings 1984-present (NMFS-reported landings limited to Nassau and Duval Counties and adjusted on the basis of the genome proportions of weakfish within the Cynoscion-complex in those counties' waters). NC: state-reported landings 1994-present. VA: NMFS-reported landings minus the PRFC-reported harvest landed in VA 1982-1992; state reported landings 1993-present (exclude Potomac River harvest). PRFC: agency-reported landings 1982-present (fish caught in Potomac River and landed in MD and VA). MD: state-reported landings 1982-present (exclude Potomac River harvest). DE: state-reported landings 1985-present. NJ: state-reported landings 2005-present. CT: state-reported landings 1995-present. RI: SAFIS landings 2005-present.

Table 4. Recreational landings (pounds) of weakfish by state, from 1982 to 2012 (NMFS 2013, except as noted below table).

| Year | FL | GA | SC | NC | VA | PRFC | MD | DE | NJ | NY | CT | RI | MA | Total |

## X. Figures

Figure 1. Estimated weakfish age 1+ biomass, fishing mortality, and natural mortality from 1982 to 2008 (NMFS 2009a, NMFS 2009b).

Figure 2. Commercial and recreational weakfish harvest (pounds), from 1982 to 2012 (see Tables 3 and 4 for source information and values).

Figure 3. Percent commercial weakfish landings (pounds) by state, from 2007 to 2012.

Figure 4. Recreational weakfish harvest and releases (number of fish), from 1982 to 2012 (see Tables 5 and 6 for source information and values).

Figure 5. Recreational weakfish landings (pounds) by state, from 2007 to 2012 (See Table 4 for source information and values).

## APPENDIX A

## 2013 Weakfish Status Update

## Summary

Non-age structured indicators of weakfish status were updated through 2012. This included exploitable biomass indices, length quality indices for DE and NJ , relative F , relative exploitation and juvenile indices. A run was made with a biomass dynamic model to estimate biomass, F, and M.

Weakfish biomass indices remain very low - slightly better than 2010-2011 but still among the lowest measured. Landings and estimated discards rose from 123 MT in 2011 to 311 MT in 2012. Fishing mortality in 2012 rose from a very low point in 2011, but is still among the lowest measured. The stock is exhibiting little response to substantial reductions in F. Length quality indices indicated that very few weakfish were reaching harvestable size; these length quality indices were similar to those observed during 1966-1969. A run of a biomass dynamic model with a predation/competition loss term indicated that $M$ is still extremely high (1.08 in 2012) when compared to $\mathrm{F}(0.13)$.

Estimation of biomass indices, fishing losses, relative $F$, and juvenile indices.
Biomass indices were formulated as outlined in the 2009 peer-reviewed assessment (see section C10, TOR 6 in the assessment; (available http://www.nefsc.noaa.gov/publications/crd/crd0915/weakfish.pdf), with some exceptions. Biomass indices (MRIP mid-Atlantic catch per trip and, DE and NJ trawl indices) were standardized to their respective 1990-2012 means (years in common for all three time-series; Table 1). This approach was recommended by the peer-review panel in 2009. The MRFSSbased estimates of Mid-Atlantic private/rental recreational CPUE (includes releases and harvest) were replaced with MRIP-based estimates. Indices outside this time-period (1981-1989 for MRIP and 1989 for NJ) were also standardized to these means (Table 1).

With the addition of 2012 biomass indices, it does not look like recovery has started. Biomass appears to have stabilized at a low level. DE and MRIP indices rose slightly in 2012 (Table 1;

Figure 1). There was a substantial rise in the NJ index during 2011, but it returned back to a low level in 2012 (Table 1; Figure 1).

Recreational and commercial harvest and discard losses were estimated using conventions of the assessment with one exception. Commercial discard losses were estimated by extending a time trend in discard estimates as a percent of commercial harvest during 2002-2007 through 2010 (Table 2). Using this trend, discard estimates increased steadily from $18 \%$ of commercial harvest in 2002 to $40 \%$ in 2010 (i.e., commercial discards more than doubled as a proportion of catch; Table 2). Commercial discard losses in 2011-2012 were arbitrarily frozen at the 2010 level ( $40 \%$ of harvest) so that they would not go up indefinitely. Ratio-based estimates of commercial discards that used all years combined rather than annual estimates (latter were variable and imprecise) were used in the 2009 assessment; however, continuing with this approach would not reflect putative changes in bycatch due to recent restrictions.

Fishing losses rose from 123 MT in 2011 to 311 MT in 2012, the first rise in estimated losses since 1998 (Figure 2). During the recovery of the stock in response to Amendments 2 and 3, losses rose to $6,500 \mathrm{MT}$ (1998) and declined afterwards. An abrupt decline occurred between 2002 and 2003, from 3,700 MT to 1,600 MT (Figure 2).

Relative F indicated that F had fallen to a very low level in 2011 - the lowest of the time-series (Figure 3). Relative exploitation in 2012 suggests that F may rise, but would still be among the lowest levels estimated (Figure 3).

Juvenile indices were updated through 2012. A series of poor year-classes during 2008-2012 were indicated by the grand means of annual standardized juvenile indices (Figure 5). An index for NY was not available for 2012.

## 2013 WEAKFISH FMP REVIEW

Table 1. Observed (Obs) biomass indices, biomass indices standardized (Standard) to 1990-2011 mean, estimated fishing losses, relative fishing mortality (F), and relative exploitation (U).

Figure 1. Weakfish biomass indices, 1981-2012. Indices have been standardized to their respective means during a common time period.

Figure 2. Total fishing losses (harvest and discards). Commercial discards for 2007-2012 estimated from 2001-2007 trend and were a constant 40\% after 2010.

Figure 3. Relative $F$ (fishing losses / 2 yr mean of indices) and relative exploitation (U; fishing losses / mean of indices).

Figure 4. Response of biomass (mean of indices) to $F$ (relative $F$ ) over major management periods

Figure 5. Juvenile indices standardized to their 1991-2012 means. Trend indicated by unweighted grand mean.

Figure 6. Delaware and New Jersey trawl survey length quality indices (Quality+ PSD)

Figure 7. Estimated F and M on weakfish during 1981-2012 .

[^0]:    ${ }^{1}$ Biomass estimates are for January 1 stock size. All mortality rates are also based on January 1 stock size.
    ${ }^{2} \mathrm{~F}$ estimates are based on age $1+$ biomass and are therefore affected by partial recruitment and can not be comparable to the F target and threshold in Amendment 4 which are for fully recruited ages only.
