Byron Young (NY)

Chris Moore (MAFMC)

Roger Pugliese (SAFMC)

December, 2002

2002 REVIEW OF THE ASMFC FISHERY MANAGEMENT PLAN FOR BLUEFISH (*Pomatomus saltatrix*)

I. Status of the FMP

The FMP for the Bluefish Fishery was adopted by ASMFC's member states in October, 1989 and approved by the Secretary of Commerce in March, 1990. This FMP, the result of a joint effort by the ASMFC and the Mid-Atlantic Fishery Management Council (MAFMC), is unique in that it represents the first management plan to be jointly developed by an interstate commission and a Federal Fishery Management Council.

ASMFC and MAFMC approved Amendment 1 to the FMP in October, 1998 and the Secretary of Commerce partially approved the Amendment on July 29, 1999. The member states were responsible for implementation of the management measures contained in the Amendment prior to January 1, 2000. On July 26, 2000 the National Marine Fisheries Service published the final rule to implement the measures contained in the Amendment. The goal of the Amendment is to conserve the bluefish resource along the Atlantic coast. Five objectives have been adopted:

1. Increase understanding of stock and fishery.
2. Provide highest availability of bluefish to U.S. fishermen; while maintaining, within limits, traditional uses of bluefish
3. Provide for cooperation among the coastal states, the various regional marine fishery management councils, and federal agencies involved along the coast to enhance the management of bluefish throughout its range.
4. Prevent recruitment overfishing.
5. Reduce the waste in both the commercial and recreational fisheries.

States with a declared interest in the bluefish FMP include all member states except Pennsylvania and the District of Columbia. Management issues are addressed through the ASMFC Bluefish Management Board and the MAFMC Coastal Migratory Species Committee. Technical advice is provided by an ASMFC Bluefish Technical Committee, annual plan monitoring and framework adjustment recommendations are the responsibility of a joint ASMFC-MAFMC Technical Monitoring Committee, and stock assessment issues are handled by the ASMFC Stock Assessment Subcommittee.

II. Status of the Stock

The most recent update on the status of the bluefish stock (Lazar 2002) indicates that the stock is overfished but overfishing is not occurring. Fishing mortality rates on bluefish peaked in 1991 at 0.760 and have steadily declined to 0.246 in 2001, below the target of 0.41 for 2002 and 2003. Stock biomass declined from a historic high of 202.2 million pounds in 1981 to 32.0 million pounds in 1995, a decrease of 84%. The total stock biomass has since risen to 39,240 mt (86,509,392 lb) for 2001, or 73% of the biomass threshold relative to Amendment 1 overfishing definitions.

Recruitment varied from 75 to 87 million fish during 1982-1984, but has declined substantially since then, with the best recent year classes recruiting to the stock in 1988 and 1989. Recruitment since 1989 has been below average, with the lowest levels occurring in 1993 and 1994, followed by a slight increase in

1995, 1996 and 1999. The NEFSC autumn inshore bottom survey (Cape Cod to Cape Hatteras) is used to predict recruitment. The survey indicated an increase in recruitment from 1994 to 1996, and in 1999 was the highest since 1989. Unfortunately, recruitment has since declined for 2000 and 2001.

The Bluefish Technical Committee recognized shortcomings of the latest assessment but concluded that it represents the “best scientific” characterization of the Atlantic bluefish stock given the currently available data. An important caveat to this assessment discussed at length by many scientists and stakeholders is that the sharp decline in landings and inshore surveys may be due to migration of adult bluefish to offshore areas presumably in response to environmental and fish population alteration in coastal areas. If indeed the epicenter of the bluefish stock has shifted to offshore waters, then inshore survey abundance for bluefish would be biased low and fishing mortality estimated by the biomass production model would be estimated high. The lack of scientific data to prove stock displacement coupled with recruitment failures observed by several monitoring surveys since 1990 suggested to take a conservative approach by NMFS, the ASMFC, and the MAFMC regarding the status of the Atlantic stock.

III. Status of the Fishery

Commercial bluefish landings, which had declined by over 34% to 10.3 million pounds in 1989, increased to 13.7 million pounds in 1990 and then dropped to the lowest value in the time series 7.1 million pounds in 1999. In 2000 and 2001, landings increased to approximately 8.0 and 8.7 million pounds, respectively. The 2001 landings were below the 1981-2001 average. The recreational bluefish catch declined steadily from a 1986 value of 30.4 million fish to 3.7 million fish in 1999, the lowest value in the time series. The 2000 and 2001 recreational catches increased to 4.9 and 6.7 million fish, respectively. Three states, NY, NJ, and NC, accounted for almost 80% of the commercial landings in 2001.

Table 2 provides bluefish commercial landings and recreational catch comparisons.

IV. Status of Assessment Advice

The most recent quantitative stock assessment was conducted by Mark Gibson and Najih Lazar from Rhode Island Fish and Wildlife in July 2002. This assessment used the dynamic population model (ASPIC) tuned to the NMFS inshore survey and the recreational catch-per-unit of effort from 1974 to 2001. The major source of uncertainty in this assessment was the lack of reliable data to characterize the state of abundance in the offshore portion of the stock.

After a series of peer reviews of bluefish assessment models the Mid-Atlantic Fishery Management Council (MAFMC) Scientific and Statistical Committee adopted the biomass dynamic model to reflect the best information on the status of the stock. Results were therefore adopted for the development of Amendment 1 to the Bluefish Fishery Management Plan.

V. Status of Research and Monitoring

Many states and the NMFS conduct fishery-independent surveys. Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Maryland, Virginia, North Carolina, and South Carolina use trawls to monitor adults and juveniles. New Hampshire, New York, Maryland, and Virginia conduct haul seine surveys. North Carolina also initiated a survey of Pamlico Sound in 2001 utilizing multiple mesh gill nets. Year class strength is monitored through the NMFS autumn trawl survey.

The NEFSC fall offshore index was explored as a possible indicator of offshore abundance of bluefish by Mark Gibson and Najih Lazar. However, the bluefish catches in the offshore survey were low and the survey showed no significant trend and high variance for the 1974-2001 period.

Commercial landings information is collected by most states through dealer or fisherman reporting programs, and fishermen in the EEZ are required to report their landings to the NMFS. North Carolina is the only state that significantly samples bluefish commercial fisheries to determine the size and age composition of the catch. Recreational harvest is monitored by the Marine Recreational Fisheries Statistics Survey.

VI. Status of Management Measures and Issues

The FMP allows a commercial quota and recreational harvest limit to reduce fishing mortality. Both are adjusted annually by the Commission and Council by the specification setting process that is detailed in Amendment 1. Amendment 1 provides a series of permitting and reporting requirements for the commercial and for hire fisheries.

Amendment 1 limits the commercial fishery to 17% of the total allowable landings each year through a commercial quota intended to maintain the traditional uses of bluefish and protect the stock from a rapid increase in commercial harvest. However, the commercial quota can be increased to 10.5 million pounds if the recreational fishery is not anticipated to land their entire allocation for the upcoming year. The overall commercial quota is divided into individual state-by-state quotas based on historic landings from 1981-1989.

The Technical Monitoring Committee is responsible for reviewing the best available data and recommending an annual commercial quota and recreational possession limit. Based on the latest stock assessment information and the rebuilding schedule contained in Amendment 1 the Technical Monitoring Committee recommended a total allowable landings (TAL) of 37.29 million pounds for 2003. The approved TAL represents a 39 percent increase relative to 2002. Both the Council and Commission voted to accept the recommendations of the Committee to establish a 10.50 million pound commercial quota and a recreational harvest limit of 26.79 million pounds.

VII. Current State-by-State Implementation of FMP Compliance Requirements

These states or jurisdictions are required to comply with the provisions of the Bluefish FMP: Maine, New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Delaware, Maryland, Potomac River Fisheries Commission, Virginia, North Carolina, South Carolina, Georgia, and Florida.

The following are specific FMP compliance requirements:

Each state must restrict the possession of bluefish by anglers to not more than fifteen fish per day, or have an ASMFC-approved equivalent conservation program (Table 4).

Each state must restrict its commercial fishery to the quota adopted under procedures specified in the FMP.

The final compliance criteria include:

Monitoring requirements for the commercial fishery

Commercial and party/charter vessel permitting requirements

Dealer permitting requirements

Annual compliance reporting

The Chair of the Plan Review Team has reviewed the states' compliance and is recommending that each state be found in compliance with respect to implementing the recreational bag limit and limiting their commercial fishery to their state quota.

VIII. Prioritized Research Needs

1. Size and age composition of the fisheries by gear type and statistical area should be collected.
2. Commercial and recreational landings of bluefish should be targeted for biological data collection wherever possible.
3. Increase intensity of biological sampling of the NER commercial and coastwide recreational fisheries.
4. Initiate research on species interactions and predator/prey relationships
5. A scale-otolith age comparison study needs to be completed for bluefish
6. Explore alternative methods for assessing bluefish, such as length-based and modified DeLury models.
7. Measures of CPUE under different assumptions of effective effort should be evaluated to allow evaluation of sensitivity of results.
8. Initiate fisheries dependent and independent sampling of offshore populations of bluefish during the winter months
9. Conduct research to determine the timing of sexual maturity and fecundity of bluefish.
10. Work should continue on catch and release mortality.
11. Any archived age data for bluefish should be aged and used to supplement NC DMF keys in future assessments.
12. Conduct research on oceanographic influences on bluefish recruitment.
13. Study tag mortality and retention rates for ALS dorsal loop and other tags used for bluefish.
14. A coastal surf-zone seine study needs to be initiated to provide more complete indices of juvenile abundance.

15. Test the sensitivity of the bluefish assessment to assumptions concerning age-varying M , level of age 0 discard, and the selection pattern.
16. Scientific investigations should be conducted on bluefish to develop an understanding of the long term, synergistic effects of combinations of environmental variables on various biological and sociological parameters such as reproductive capability, genetic changes, and suitability for human consumption.
17. Studies on the interactive effects of pH, contaminants, and other environmental variables on survival of bluefish.

TABLE 1. Estimated number of bluefish caught and the estimated number of bluefish landed by marine recreational fishermen each year, 1981 to 2001.

State	Catch ('000)	Landing ('000)
1981	31,261	23,888
1982	27,220	23,724
1983	30,137	24,884
