State of Stock: Relative to the biological reference points proposed by the working group (WG) in the 2005 SARC, the bluefish stock is not overfished and overfishing is not occurring $\quad\left(1 / 2 \mathrm{~B}_{\mathrm{MSY}}=73,526 \mathrm{MT}\right.$; $\mathrm{F}_{\text {MSY }}=0.19$ ). This conclusion is based on a 2006 biomass estimate of 139,496 MT and $F=0.15$ from the ASAP model results. Fishing mortality rates $(F)$ estimated in ASAP using state and federal indices show a low $F$, an increasing trend in population biomass, and an increasing trend in population numbers. January 1 population abundance estimates show a general increase in overall abundance since 1997. Abundance estimates peaked in 1982 at 175 million fish, declined to 57 million in the mid-1990s and has since increased to 88 million fish.

Forecast for 2008: Forecast yield in 2008 at status quo F (0.15) was 14,464 MT, which includes recreational discards with $15 \%$ mortality. The forecast is based on a 2007 yield of 13,697 MT.

## Catch and Status Table (weights in '000 MT): Bluefish

| Year | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | Max | Min | Mean |

Stock Distribution and Identification: Bluefish are highly migratory, pelagic species found along the U.S. Atlantic coast from Maine to Florida, but generally are found inshore north of the Carolinas only in warmer months (Beaumariage 1969; Lund and Maltezos 1970; Shepherd et al. 2006). Bluefish in the western North Atlantic are managed as a single stock (NEFSC 1997; Fahay et al. 1999). Genetic data support a unit stock hypothesis (Graves et al. 1992; Goodbred and Graves 1996; Davidson 2002). For management purposes, the ASMFC and MAFMC define the management unit as the portion of the stock occurring along the Atlantic Coast from Maine to the east coast of Florida.

Catches: Bluefish are one of the most sought after species by recreational fishers along the Atlantic Coast. In 2006, recreational anglers along the Atlantic Coast harvested nearly 7,663 metric tons (MT) of bluefish (Figure 1). Recreational landings have ranged from a low of 3,744 MT in 1999 to a high of 43,222 MT in 1981. Landings from the commercial bluefish fishery have been consistently lower than the recreational catch (Figure 1). Regional variations in commercial fishing activity are linked to the seasonal migration of bluefish. Commercial landings decreased from 7,500 MT in 1981 to 3,300 MT in 1999. Commercial landings have been regulated by quota since the implementation of Amendment 1 in 2000. In 2000 and 2001, landings increased to approximately $3,600 \mathrm{MT}$ and $3,900 \mathrm{MT}$, respectively, but declined again in 2002 and 2003 to 3,100 MT and 3,400 MT, respectively. Preliminary landing estimates for 2006 decreased to 2,900 MT (Figure 1). Gill nets are the dominant commercial gear used to target bluefish and account for over $40 \%$ of the bluefish commercial landings from 1950 to 2003. Other commercial fishing gears including hook \& line, pound nets, seines, and trawls, collectively account for approximately $50 \%$ of the commercial landings.

Data and Assessment: The ASMFC Bluefish Stock Assessment Sub-Committee compiled the commercial, recreational data, and ageing information for use in updating the assessment model. The majority of commercial sampling since 1997 occurred in North Carolina and Virginia, where a large proportion of the landings are taken. Recreational landings data, length data, and discard estimates were collected from the

MRFSS survey. Age data were used from Virginia’s cooperative ageing program and consisted of seasonal age data (spring and fall age keys). State agencies between Massachusetts and Florida conduct annual marine finfish surveys and the indices, partitioned by age, were used in a forward projecting catch at age model. Indices included in the model were from the NMFS fall survey (ages 0-6+), CT trawl survey (ages $0-6+$ ), NJ trawl survey (ages $0-2$ ), DE trawl survey (ages 0-2), MRFSS recreational catch per angler (ages $0-6+$ ), and SEAMAP survey (age-0, data unavailable for 2006). A $15 \%$ mortality rate was applied to recreational discards and no commercial discards were estimated for inclusion in this assessment.

Biological Reference Points: The current biological reference points for Atlantic coast bluefish in the FMP $\left(1 / 2 \mathrm{~B}_{\text {MSY }}=53,750 \mathrm{MT}\right.$ and $\left.F_{\text {MSY }}=0.31\right)$ were based on a surplus production model that has since been rejected during the SAW 39 review. Biological reference points presented at SARC41 were used in this assessment for comparison to current stock status ( $1 / 2 \mathrm{~B}_{\mathrm{MSY}}=73.5$ million lbs or $33,339 \mathrm{MT}$; $F_{\mathrm{MSY}}=$ 0.19 ) (Table 1). The rebuilding deadline for bluefish is 2010, at which point the stock is expected to meet or exceed biomass at $\mathrm{B}_{\mathrm{MSY}}$ ( 147,051 MT). The projected biomass estimate exceeds that level in 2009 ( 147,925 MT). The current $F$ of 0.15 is below the SARC 41 approved $F_{\text {MSY }}$ of 0.19 (note: the $F_{\text {MSY }}$ estimate from the recent updated ASAP model is 0.11 ). Therefore, it is concluded that bluefish is not experiencing overfishing. The current estimate of biomass equals 139,496 MT, which would not be considered overfished under the FMP definition or the $\mathrm{B}_{\text {MSY }}$ value approved by SARC 41.

Fishing Mortality: Fishing mortality estimates in ASAP are based on a separability assumption. $F_{\text {MULT }}$ is the product of $F$ at age and selectivity. The $2006 F_{\text {mult }}$ value equals 0.15 . The trend in $F$ has steadily declined since 1987 when $F$ reached 0.38 .

Total Stock Biomass: Biomass estimates peaked in 1982 at 303.0 thousand MT, then declined to 84.2 thousand MT by 1996 before increasing to the 2006 level of 139.5 thousand MT.

Recruitment: Recruitment estimated in the ASAP model has remained relatively constant since 2000 around 21.8 million age-0 bluefish. The 2006 recruitment estimate increased to 29.9 million fish.

Modeling: The subcommittee updated the ASAP model that was approved in the $41^{\text {st }}$ SAW peer-review. The bluefish data were truncated to an age-6+ category to reduce the influence of ageing error and to reduce the bimodal nature of the catch-at-age distributions. The ASAP model allows error in the catch-atage as well as the assumption of separability into year and age components making it better at handling the selectivity patterns and catch data from the bluefish fishery.

Special Comments: The highly migratory nature of bluefish populations and the recruitment dynamics of the species create a unique modeling situation. Migration creates seasonal fisheries with unique selectivity patterns resulting in a bimodal partial recruitment pattern. This pattern has been identified in previous assessments as a source of uncertainty in the results. The migratory pattern in bluefish also results in several recruitment events. A spring cohort, originating south of Cape Hatteras, NC during spring migrations, and a summer cohort originating in the offshore Mid-Atlantic Bight result in a bimodal age-0 size distribution. It has been hypothesized that the success of the spring cohort controls the abundance of adult bluefish. The variable intra-annual recruitment pattern, limited ageing data and lack of commercial discards also contribute to the uncertainty in the assessment results.
