## Bluefish Assessment Summary

ASMFC Bluefish SASC, June 2010

State of Stock: Relative to the biological reference points proposed by the working group (WG) in the 2005 SARC, the bluefish stock is not overfished and overfishing is not occurring ( $1 / 2 \mathrm{~B}_{\text {MSY }}=73,526 \mathrm{mt}$; $\mathrm{F}_{\text {MSY }}=0.19$ ). This conclusion is based on a 2009 biomass estimate of 125,990 MT and $F=0.18$ from the ASAP model results. Estimates from ASAP using state and federal indices show a low fishing mortality rate $(F)$ and an increasing trend in population biomass. January 1 population estimates show a general increase in abundance since 1997. Abundance estimates peaked in 1982 at 173 million fish, declined to 56 million in the mid-1990s and have since increased to 89 million fish in 2007. Abundance in 2009 declined to 71.3 million fish.

Forecast for 2010: Forecast yield in 2011 at status quo F (0.18) was $10,021 \mathrm{mt}$, which includes recreational discards with $15 \%$ mortality. The forecast is based on a 2010 yield of $10,272 \mathrm{mt}$.

## Catch and Status Table (weights in '000 mt): Bluefish

| ${ }^{3}$ Min, max, and mean total catch since 1982. |  |  |  |  |  |  |  |  |  |  |

Stock Distribution and Identification: Bluefish are highly migratory, pelagic species found along the U.S. Atlantic coast from Maine to Florida, but generally are found inshore north of the Carolinas only in warmer months (Beaumariage 1969; Lund and Maltezos 1970; Shepherd et al. 2006). Bluefish in the western North Atlantic are managed as a single stock (NEFSC 1997; Fahay et al. 1999). Genetic data support a unit stock hypothesis (Graves et al. 1992; Goodbred and Graves 1996; Davidson 2002). For management purposes, the ASMFC and MAFMC define the management unit as the portion of the stock occurring along the Atlantic Coast from Maine to the east coast of Florida.

Catches: Bluefish are one of the most sought after species by recreational anglers along the Atlantic Coast. In 2009, recreational anglers along the Atlantic Coast harvested nearly 6.2 thousand metric tons (mt) of bluefish (Figure 1, Table 1). Recreational landings have ranged from a low of 3,744 mt in 1999 to a high of $43,222 \mathrm{mt}$ in 1981. Landings from the commercial bluefish fishery have been consistently lower than the recreational catch (Figure 1, Table 1). Regional variations in commercial fishing activity are linked to the seasonal migration of bluefish. Commercial landings decreased from 7,500 mt in 1981 to $3,300 \mathrm{mt}$ in 1999. Commercial landings have been regulated by quota since the implementation of Amendment 1 in 2000. In 2000 and 2001, landings increased to approximately 3,600 mt and 3,900 mt, respectively, but declined in 2002 and 2003 to $3,100 \mathrm{mt}$ and $3,400 \mathrm{mt}$, respectively. Landing estimates for 2009 increased to $3,151 \mathrm{mt}$ (Figure 1, Table 1). Gill nets are the dominant commercial gear used to target bluefish and account for over $40 \%$ of the bluefish commercial landings from 1950 to 2003. Other commercial fishing gears including hook \& line, pound nets, seines, and trawls, collectively account for approximately $50 \%$ of the commercial landings.

Data and Assessment: The ASMFC Bluefish Stock Assessment Sub-Committee compiled the commercial, recreational data, and ageing information for use in updating the assessment. The majority of commercial sampling since 1997 occurred in North Carolina and Virginia, where a large proportion of the landings are taken. Recreational landings data, length data, and discard estimates were collected from the

MRFSS survey. Age data were used from Virginia's cooperative ageing program and consisted of seasonal age data (spring and fall age keys). State agencies between Massachusetts and Florida conduct annual marine finfish surveys and the indices, partitioned by age, were used in a forward projecting catch at age model (ASAP). Indices included in the model were from the NMFS fall survey (ages 0-6+), CT trawl survey (ages $0-6+$ ), NJ trawl survey (ages $0-2$ ), DE trawl survey (ages $0-2$ ), MRFSS recreational catch per angler (ages 0-6+), and SEAMAP survey (age-0). CT trawl survey indices were not estimated for 2008 but were included (ages 0-6+) for 2009. A $15 \%$ mortality rate was applied to recreational discards and no commercial discards were estimated for inclusion in this assessment update.

Biological Reference Points: The current biological reference points for Atlantic coast bluefish were developed for review at SARC 41 and are used in this assessment for comparison to current stock status $\left(1 / 2 \mathrm{~B}_{\mathrm{MSY}}=73,526 \mathrm{mt} ; \mathrm{B}_{\mathrm{MSY}}=147,051 ; F_{\mathrm{MSY}}=0.19\right)($ Table 2$)$. The current $F$ of 0.18 is below the SARC 41 approved $F_{\text {MSY }}$ of 0.19 . Therefore, it is concluded that bluefish is not experiencing overfishing. The current estimate of biomass ( $126,121 \mathrm{mt}$ ) would not be considered overfished under the FMP definition or the $\mathrm{B}_{\mathrm{MSY}}$ value approved by SARC 41 .

Fishing Mortality: Fishing mortality estimates in ASAP are based on a separability assumption. $F$ at age is the product of $F_{\text {mult }}$ and selectivity. Full selectivity prior to 1994 was achieved at age 1 while full selectivity since 1995 was estimated as age 2 . The $2009 F_{\text {mult }}$ value equals 0.18 . Fishing mortality steadily declined from 0.42 in 1987 to 0.21 in 2002. With the exception of 0.18 in 2009, fishing mortality has remained steady since 2000 with an average $\mathrm{F}=0.24$.

Total Stock Biomass: Recent mean biomass estimates peaked in 1982 at 288.2 thousand MT, then declined to 79.5 thousand MT by 1994 before increasing to the 2009 level of 126.0 thousand MT.

Recruitment: Recruitment estimated in the ASAP model has remained relatively constant since 2000 around 25.0 million age-0 bluefish, with the exception of a relatively large 2006 cohort estimated as 32.3 million fish. The 2009 recruitment estimate was well below average at 10.8 million fish.

Modeling: The subcommittee updated the ASAP model that was approved in the $41^{\text {st }}$ SAW peer-review. The bluefish data were truncated to an age-6+ category to reduce the influence of ageing error and to reduce the bimodal nature of the catch-at-age distributions. The ASAP model allows error in the catch-atage as well as the assumption of separability into year and age components making it better at handling the selectivity patterns and catch data from the bluefish fishery. In the present configuration of ASAP, selectivity was estimated for two periods before and after 1994/1995.

Special Comments: The highly migratory nature of bluefish populations and the recruitment dynamics of the species create a unique modeling situation. Migration creates seasonal fisheries with unique selectivity patterns resulting in a bimodal partial recruitment pattern. This pattern has been identified in previous assessments as a source of uncertainty in the results and has been held constant in the model. The migratory pattern in bluefish also results in several recruitment events. A spring cohort, originating south of Cape Hatteras, NC during spring migrations, and a summer cohort originating in the offshore Mid-Atlantic Bight result in a bimodal age-0 size distribution. It has been hypothesized that the success of the spring cohort controls the abundance of adult bluefish. The variable intra-annual recruitment pattern, limited ageing data, recent changes in the NEFSC trawl survey and lack of commercial discards also contribute to the uncertainty in the assessment results.
